THE PSYCHOLOGY OF PROGRESSIVE DEAFNESS

GORDON BERRY, MD
WORCESTER, MASS

Sir Joshua Reynolds, the painter, was hard of hearing. He made several portraits of himself with his ear trumpet. Of his deafness, Goldsmith wrote in his poem "Retaliation"

To combs averse, yet most skillfully steering
When they judged without skill, he was still hard
of hearing,
When they talked of their Raphaels, Corregios
and stuff,
He shifted his trumpet, and only took snuff

Here was a man who used his deafness as an escape. Fortunately, his life was so filled with purpose and accomplishment that he resorted to this escape more as a convenience than as a necessity. George Meredith accepted his infirmity in a more chastened fashion, for in 1908 he wrote to Mrs Saleeby 'And worse—the Sexton has filled one of my ears, and seems to be at work on the other, so that conversation is not smooth or pleasant for me, and can hardly be agreeable for my friends. Therefore I do not encourage them to come here though I love them.' Lord Chesterfield wrote fairly optimistically at first "I am very deaf, and consequently alone, but I am less dejected than most people in my situation would be." But after three years of buffeting, he said "My deafness is extremely increased and duly increasing and cuts me wholly off from the society of others, and my other complaints deny me the society of myself." Here are three illustrative quotations (furnished by Mrs Harriet Montague of the Volta Bureau in Washington) giving concrete evidence of the tragedy that stalks in the wake of every progressive form of deafness. Are otologists content with applying the limited curative means at their disposal, and then do they turn patients away to be the victims of despondency on the one hand or of charlatans on the other? The otologist is the first person to whom the hard of hearing trustfully turn. This discussion will deal with the behaviors and reactions of these unfortunate persons who daily seek the counsel of the otologist. I cannot speak with the authority of the psychologist. One must turn to Karl Menninger or Paterson or Rudolph Pinner for that. Rather do I speak from the point of view of one who is himself hard of hearing, and whose interest both as a victim and as an otologist has just naturally brought him into intimate contact with that splendid band of workers, who through the

American Federation of Organizations for the Hard of Hearing are pushing forward on a nationwide front to help themselves and their handicapped fellows. Those who would read a triumphant story of human accomplishment against odds are urged to review the gripping story as told by the secretary of the organization Miss Betty C Wright, before the American Otological Society on June 19, 1931¹

CHANGES IN BEHAVIOR AS DEAFNESS PROGRESSES

Scientifically, the otologist is concerned with whether his patient has a nerve deafness, or a catarrhal form, or whether there is an otosclerotic heredity. In this discussion I must skip over the cause and nature of the disease and deal only with the behavior changes as deafness progresses through different ages.

As a Child—The onset is gradual. There is no concern. Neither child nor parent nor doctor appreciates the grave prognosis. The second stage finds a beginning handicap. The father thinks Tom is inattentive, the mother calls it preoccupation, the teacher suspects stupidity, his comrades think he does not care or that he is queer or self-centered. If the parents are busy and nonanalytic, the deafness may progress even to a 30 per cent loss with no one understanding what is the matter. The boy with no standard of comparison will not appreciate his own deafness at first, but will blame lowered voices or adventitious noises for his failure to hear. Finally, the realization forces itself on him that something is wrong. He will tend to evade this conclusion, he will try to cover up and deceive others. This deceit phase may be carried to extremes and keeps cropping out in his later life. He becomes very adept and may fool parent and teacher and playmate long after his trouble should have been found and corrective measures and mental adjustments instituted. But though he has covered up his malady he has paid the price. Other explanations for his failure to hear had to be offered. The child whose remarkable alertness catches the meaning when but half of the sentence is heard suffers the ignominy of a suspected mental deficiency. In school, the easiest way to answer a question that he does not hear is 'I don't know,' and a zero mark for that day's lesson is the inevitable consequence.

In Adolescence—By this time Tom has passed into the next stage where his deafness is known by all. He now carries out the same cover-up policy by trying to minimize the severity of his handicap. No normal person wishes to attract attention to any infirmity. This is axiomatic. So he may try to show how well he can hear by sitting far back instead of in front. Rather than say "what," he will guess what was said, often

¹Read before the Section on Laryngology, Otolaryngology and Rhinology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.

erroneously, having missed the key word or idea, and thus be unfairly credited with stupidity.

At this point, the characteristic inferiority complex of the hard of hearing creeps in. He finds himself not as able and efficient as his fellows. He is inferior and tries to hide it, he becomes the more aware of it as he broods and dwells on it. Aggressiveness may enter here. The boy is not so clever in his studies, or not so acceptable on the baseball field, in football or in shooting marbles. He never receives the commendation of his fellows, he decides that something must be done about it. He may tell a startling lie. Yes, he is found out and even gets punished, but the important thing is that he gains a compensating satisfaction in calling attention to himself. Or he may steal or swear or fight. Thus he secures the center of the stage. This is healing balm for the boy who has been on the sidelines. The chronic bad boy, the thief, the firebug or the bully may be here in the making. One patient of mine, nearly totally deaf and with almost no education, had found his satisfaction in boxing, and at about 18 years of age was earning his own way as a professional pugilist. In the child, then, one finds a baffled personality, discouraged, uncertain, perplexed, timid and afraid, or aggressive, self-centered and blundering. In the adolescent, defeatism and isolation contribute their tragedy, or rebellion is added. In his school work, successive failures take him back till his classmates are younger and smaller than he. Of course a 15 year old boy is a misfit in 10 year old surroundings, and a misfit he may continue for the rest of his life unless the otologist, who should be his best friend, so advises that educational adjustments ready and available can be applied.

The Young Adult — But supposing the hearing impairment is not considerable until the early twenties. This is the more frequent period for adult progressive deafness to become established. Fortunately, education has been acquired. A trade or profession has been learned, perhaps one in which good hearing is well-nigh essential for the girl may be a stenographer or a telephone operator, the boy may be a sales clerk, an insurance agent or a teacher. What are their mental reactions as deafness stalks near? Here resistance and rebellion are more apparent. The person is likely to hide it as a dread secret which must not be known. Long after friends have noticed it, ostrich-like she thinks she has hidden most of her infirmity from public knowledge. Finally, her parents or friends force her to the otologist's office, where she may give no history of any ear trouble or say that some wax is bothering which she desires removed because it dulls her hearing just a little. Examination may show the characteristic lack of cerumen and a bilateral 40 per cent loss of hearing, with but little help available. If a cure could be assured in three treatments, she would try it. But if the tonsils should be removed or a nasal condition should be corrected, she says why bother, she is not sick enough for that. If the otologist senses that she is not facing and should face the issue, and proceeds to tell her the facts without mincing, she will insist "I am not deaf, I can't be deaf", or she tentatively accepts the verdict and there is a scene which continues on at home for many days. Finally she works out of her despair, but not into the otologist's office. She says that the doctor simply tried to scare her and did not know what he was talking about. She returns to her old life and continues her many petty deceptions. A stenogra-

pher blames her employer's mumbling voice. A telephone operator insists that she hears the numbers, but an increasing list of errors are checked against her. The normal school student who came to the office the other day complained because her teachers lowered their voices purposely when they addressed her, and the mother shared in this persecution idea. There is throughout this period a tendency not to face fact and to seek adjustments but to go on as before, hoping that "mamma will fall from heaven" and things will work out all right. Bitterness comes, but youth is resilient. Inferiority may come, but if it has not entered until now, it is likely to wait until the handicap is more advanced. When marriage is contemplated, in my limited experience there is a greater likelihood of facing facts and trying to anticipate future probabilities. As between the male and the female, up to this point of, say, 25 years of age, the reactions to encroaching deafness are nearly parallel, but by now the female takes it harder than the male, and this becomes increasingly so as middle life is approached.

Friends do so little to help. In their popular book "Your Hearing,"² Dr Wendell C Phillips and Dr Hugh Grant Rowell find it natural to dislike the hypocritic or deafened "What a nuisance they are, we think. So we ostracize them cruelly. They can't help becoming introverts. From introversion to paranoia is no long step. The shut-in individual may easily develop a twisted philosophy of life, based on persecution. The asocial traits appear."

In the Prime of Life — If the hearing handicap has troubled but little until the forties, it now handicaps the woman more. If she is in some administrative task, she then runs parallel to the man. But if she is in the home or active in society or in club work or in church and charity activities, this deafness troubles her much more than it does the man. His business world has learned to accept him at his worth and will adjust itself somewhat to his handicap, her world is wider and more superficial in its contacts and will not help her. She has the choice of making the adjustments, or of isolating herself. In the social amenities she is under a constant handicap. Intimate confidences with a friend are nearly impossible, unless written. In the interplay of general conversation, she has the choice of monopolizing it, for only then does she know all that is being discussed, or she can keep silent. Probably she will absent herself from one activity and then another, and her former broad interests and vital contacts will contract and narrow until her limited and self-centered world finds her supersensitive, easily upset, perhaps emotional, and suspicious. Forced back into the home, she is impatient, selfish, unhappy and even morose.

Occasionally the man takes it very hard. The two things he dreads are failure to carry on in his active man's society, and the inability to continue as the provider. Often a severe tinnitus is superimposed which constantly reminds him of his deafness, he may brood on his troubles, and insanity or even suicide result. Dr MacLaurin of Australia, in "Mere Mortals,"³ says that Martin Luther was tormented by infernal crashings and whistlings in his ears that certainly did not come from heaven and, therefore, he was certain, must be from Satan himself. Luther used to wake out of a sound sleep and yell back at his devil and once he

threw an ink pot at him, and nussed him, as shown by a spot which is still to be seen on the wall of the Warthburg. These noises were accompanied by attacks of giddiness which sometimes caused him to fall from his stool and rendered work impossible. As he grew older, his deafness became pronounced and was accompanied by severe cardiac distress. All these things were to Luther certain evidence that his personal devil was attacking him. Dr MacLaurin thus wonders whether his severe timitus was not measurably the cause of his militant religious zeal and whether there would have been any Reformation if Martin Luther had not had Meniere's disease.

In Advanced Years—A consideration of the deafness which first comes in, say, the sixties should be included. This is usually a nerve form. Here a matter-of-fact view may consider the patient lucky in having lived his life and done his bit before the handicap comes. But hard indeed is his lot if the deafness is at all considerable. Confusing noises are particularly trying in this type of deafness, and group conversations or telephone exchanges are difficult or impossible. Here the patient finds himself infirm ere his time and forced to drop out of church, club, committee and social life just when they are most interesting and indeed essential to happiness. He who is deafened at 65 feels as though he had reached the four score years of the psalmist when there is much labor and sorrow, and, contrary to the Scripture, it is not soon gone and there is no flying away. Lucky is he who has his hobbies, delights in reading or writing, in carpentering or gardening. Creative music is not shut away, for symphonies can continue to sing just as clearly in the mind of a deaf Beethoven as they can for the hearing. Deafness may help concentration, as it did with Thomas Edison. But for the noncreative mind an encroaching senile deafness is a great trial, adjustments are well-nigh impossible, a narrowing enforced isolation makes a sunny optimist into a chastened dependent. Fortunate is he or she if a congenial cotraveler on life's road completely understands and gaily keeps step, through sunshine or shadow, down through the ebbing years.

ADJUSTMENTS

Nature is resilient. Man shares in this attribute. And the younger he is, the easier the adjustment. When a child is born deaf, the process is very different. Education, the growing up among hearing people, the life that must be lived among those who have a sense that he does not possess, is, of course, a laborious and difficult task. But at least this child is not sound-conscious and never can completely realize the music he has lost.

Mechanical Measures—The hard of hearing child must make many adjustments. Under kind parental and trained teacher guidance, this can be done. He learns lip-reading readily.⁴ Group ear-phones are available for teaching purposes. In this modern day a great deal of the burden has been lifted from these handicapped persons. As his age advances, lip-reading is used and is found to be a great help, but it is not quite as easily acquired. And as the acoustic engineer makes electrical hearing aids more sensitive, less expensive and easier to carry the hard of hearing adult finds them increasingly serving his need. They have their

drawbacks, granted. But what a boon they are to him who can and will use them! These are the two crutches that the hard of hearing must rely on.

Vocational Measures—Vocational adjustments offer an interesting study. Let me deal with two types: (a) the youth who knows in advance that this handicap will exist and must be reckoned with, and (b) the adult whose trade has already been learned and for which his impairment now suddenly unfits him. Type a. For any young man, the outlook is by no means bad. There are relatively few trades or professions in which impaired hearing is of itself a great handicap, once the social and individual adjustments have been made. For instance, in the practice of medicine the expert mechanics of a back brace, of a tonsillectomy, of an ocular refraction or of an appendicectomy are not affected by one's auditory capacity. Type b. For the adult who has learned a trade in which good hearing is essential, a change must be made, and this is hard. Also, the deafened should "secure work where the hearing will be best conserved."² Experts in vocational adjustments for the hard of hearing⁷ urge that a man do, if possible, what he is really fond of. But without a great urge toward one specific trade, the hard of hearing man would be foolish in this keenly competitive age to burden himself with a known handicap, for there are so many tasks where good hearing, though an advantage, is not essential.

It has been pointed out and should be emphasized that the difficulty one thinks of when the vocation of a hard of hearing man is discussed is chiefly a social and psychologic rather than a vocational difficulty. If he can read and carry out his written orders or understand his foreman, his deafness makes him a no less skilled craftsman. In business and the professions, assistants with normal ears are available to make up completely for the individual lack. In most instances, the problem is one of human intercourse. When these social adjustments have been made, the handicap is largely taken care of.

Not Always a Liability—Indeed, impaired hearing may be an asset rather than a liability. A deafened book-keeper or machine operator mends her business and does not spend her time or her neighbor's time in gossip. A handicapped laborer who knows a trade will tend to stick on the job and not leave in search of an easier and better paid task. Three assets may be mentioned: (a) Deafness decreases distractions and increases concentration, (b) it fosters constructive thought, though unfortunately the person may not have the creative genius to respond, and (c) it can and in some cases it does increase the interpretative capacity of the other senses. When seeing an expert lip-reader perform, one realizes at once that here is a keenness of visual perception and appreciation that is well-nigh past comprehension. It is questioned as to whether the actual sense responses are made keener. Certain it is that the mental appreciation of what one touches and sees can be increased. Is it not possible that vocations demanding keenness in color combinations or in perfumery perception or in taste blends or in tactile acuity will find the best performers in the ranks of the hard of hearing? Nature delights in compensations. Does not he who conquers an adversity, never mind of what nature, build for his soul a 'statelier mansion'? Joseph Holland, the famous actor, would not be downed when

at the height of his career his hearing failed him.⁸ Although he could not hear his fellow actors' voices, he continued for some years to act in the plays with which he was familiar. "When the action permitted him to face the speaker, his eyes told him when it was his turn to speak. When his back was turned he counted at measured pace, after having patiently worked out the number of beats each speech of the others would occupy." No one in the theater realized his difficulty so long as he continued to play the old parts. Thomas Edison claimed that his deafness was a great help in eliminating much of the needless gossipings of life and in permitting him to concentrate. The deaf Beethoven said, "I will grapple with my fate, it shall never drag me down" and wrote some of his sublimest symphonies after he could no longer hear a note. Were these the results of this law of compensation? Such historical illustrations seem to prove that impaired hearing offers no excuse for failure.

Social Adjustments—I now return to my earlier premise that the handicaps are primarily in human intercourse. One philosophic friend says that his deafness does not rob him of his beer along life's road, it is just the froth he cannot have. Horace Howard Furness gave up perhaps more than the froth when in declining an invitation to dine he wrote to Charles Elton Norton "Thanks, more than would fill this sheet, for your hospitable intentions, but it is many, many years since I formed a resolution to sit at no table but my own. I am so deaf that I must either wholly listen, or wholly eat and the attempt to divide the two always causes embarrassment to my host and to me, and since nature has thus instructed me to remain in the background, I take the hint and obey her request." And this was the man who ultimately won lasting fame because his deafness forced him to abandon the bar and to take up the great work of his life, the *New Variorum Shakespeare*.

The crux of the difficulty is not so much the exact degree of deafness (though I would be the last to belittle that) for lip-reading and hearing aids⁹ are splendid helps. Nor is the handicap purely a vocational one, though again, the road to success may be rough and steep. The chief trouble is in the person's social relations. Henry Hunter Welles of Columbia Teachers College, in a recent research¹⁰ divides them sharply into the adjusted and the unadjusted. The victim may curse his neighbors, his parents or his God as Pauline Leader did in her remarkable and tragic autobiography, "And No Birds Sing,"¹¹ or he may look out over the world and find it amusing and lovely, as Earnest Elmo Calkins does in his fascinating and whimsical tale, "Louder Please,"¹² or Persis Vose in those delightful sketches "Say It Again."¹³ Much, very much, depends on the influences brought to bear on this unfortunate person but if only a parent or a dear friend or an understanding doctor once leads him "into green pastures and beside still waters," the rest he can do. Self-satisfaction, success and happiness are assured to him who overcometh.

In Harold Hays' excellent book "The Modern Conception of Deafness,"¹⁴ Miss Betty Wright discusses the "by-products" in this constructive effort.

Not every student of lip-reading becomes a good lip reader but the by-products 'possess a market value of their own. These by-products often bring self-reliance, independence, courage to "carry on", a different outlook on life and increased joy in living, a quickening of the mental faculties, better understanding of human nature, a diminution of sensitivity and the loss of a feeling of inferiority.

The by-products of the use of hearing aids are more tangible than those of lip reading and none the less valuable. The sound of a loved voice, the babble of children at play, the music of the great out of doors, the beautiful phrases falling from the lips of some great lecturer, conversations in the twilight, the talk around the table—are not these compensations enough for the inconvenience of a hearing aid?

How do I know this readjustment is possible? Attend with me one of these conferences of the hard of hearing and see for yourself the enthusiasm and optimism that there abounds. Why? The answer may evade one at first. What heaven has changed the self-centered, timid, unhappy patient into this buoyant, sunny personality? Is it not the age old philosophy of loving your neighbor as yourself—what else? Mrs. Jones used to spend most of her time being sorry for herself and wondering how her former friends could manage without her, now she is so busy thinking and planning for others that there is no time or desire for introspection. Every one wishes to express oneself and enjoy the commendation and appreciation of one's comrades. So does Mrs. Jones who has joined the local League for the Hard of Hearing and now plays bridge, listens to lectures through the group ear-phone, helps an unemployed fellow-sufferer secure a job, assists in the acoustic testing of school children, serves on committees, in short expresses herself and cheers her neighbor. Why shouldn't she be happy?

Assurance Needed—But it is not as simple as it sounds. There are many discouragements and setbacks. The warm understanding of the otologist can do so much when this confused sufferer strikes these bumps. No, it is not sympathy that he wants. Do not apologize for him. Rather assure him. Ask more of him. Give him his "Message to Garcia" and expect him to go through and make good. If one's confidence is genuine, he will not fail.

The Philosophy of the Hard of Hearing—In an effort to put this principle into brief and concrete form, I prepared certain rules of conduct which seemed basic and which, with an allowance for their being formulated for the members of the Federation for the Hard of Hearing, will apply to almost every deafened person who seeks an otologist. I called them "the nine commandments." They try to epitomize the philosophy of that hard of hearing man or woman who endeavors to face and surmount his handicap. They will serve as my closing summary. If they bring to the normally hearing greater sympathy and understanding, or to the hard of hearing greater courage and happiness, I am content.

The Nine Commandments for the Hard of Hearing

1 Thou shalt frankly confess thy deafness to thyself and before thy fellow men. Let there be no deceit nor false pride.

¹⁴ Hays, Harold. *Modern Conception of Deafness*. St. Louis: Laryngo scope, 1933.

¹³ Vose, Persis. *Say It Again*. A Book of Essays. Portland, Maine: The Southworth Press, 1931.

2 Thou shalt not covet thy neighbor's hearing but shalt rejoice that thou livest in an age when thy handicap can be made so small

3 Early and again shalt thou consult thy otologist and accept every scientific aid he can render

4 Eschew the quack and his devices Easy and broad is the way to his door and many there be that find it

5 Thou shalt join and work for a League for the Hard of Hearing where thou wilt receive encouragement and stimulation for thyself and wilt find happiness in serving thy brother Thus wilt thou march forward with the Federation army that is alleviating deafness throughout the world

6 So love thy neighbor that thou do everything in thy power to help him when he would have speech with thee To this end

7 Thou shalt study lip-reading, in season and out of season

8 Thou shalt secure and use the best ear-phone thou canst discover

9 Triumphantly shalt thou rise above thine infirmity, and so conduct thy life that the world hath need of thee

36 Pleasant Street

ABSTRACT OF DISCUSSION

DR WENDELL C PHILLIPS, New York If the otologists of the country can once get the proper conception of what this service to the hard of hearing really means and then render that service, a great step will have been taken in solving the numerous problems of those with defective hearing I know that many otologists are generally willing to cooperate but it seems impossible to get them to make a practical application on their patients A recent experience will serve to illustrate A woman, aged about 35, suddenly found that the defect in her hearing had reached the point where she feared it might become serious She consulted an otologist in New York, a man who, I supposed, knew what the service idea of the otologist should be She stated that he made a careful examination, told her quite a bit about her case and said he did not think treatment would do any good—that she had probably better investigate hearing devices He then told her not to forget to leave a check as she went out The time has come for otologists to inform themselves regarding the wonderful opportunity they have for rendering a real service to a class of people who need that service Otologists should associate themselves in the service side of the hearing problem with the local leagues for the hard of hearing There are more than 120 of these in the United States that open their doors to the hard of hearing The time has come for psychiatrists to enter into this field because of the peculiar psychology manifested by these patients Finally I wish to emphasize the importance of testing the hearing of school children

DR JOHN F CURTIN, Minneapolis Experience has provided me with a certain method of handling patients with a chronic progressive deafness First is the diagnosis, second a discussion with the patient, in language he or she can understand, of the nature of the impairment I attempt to put myself in the patient's place with his reaction to a frank survey of the possibilities of his hearing condition I ask him to consult a capable internist to evaluate his general physical state and to administer any therapy needed I attempt to correct any local pathologic condition in the ear, nose or throat that suggests a reasonable relationship I enlighten him on the field of aural quickery The patient is then guided in his needs for lip-reading the use of hearing aids and the like He is asked to report every six months for reexamination and advice Most of the patients report to me at regular intervals and I feel that I help them maintain the proper psychologic attitude toward their problem

DR GEORGE E SHANBAUGH, JR Chicago Deafened persons are loath to believe that they are as deaf as they are They often know, subconsciously, that their deafness is perma-

nent, yet for a long time they will not admit this to themselves, and they try out one form of treatment after another until, finally, they have passed through the psychologic storm of refusing to admit the truth and emerge into the calm of acceptance of their handicap, when they can at last concentrate on lip reading, electrical hearing aids and social contacts renewed through leagues for the hard of hearing In a recent study of 165 severely deafened adults, I found that 115 had progressive deafness which came on insidiously in early or middle adult life and was not accompanied by symptoms of otitis media or tubal occlusion All of the 115 presented the Bezold triad of conduction deafness One third had slight changes in the drum membrane, the remaining two thirds had entirely normal drum membranes The treatments that these 115 typical cases of otosclerosis had undergone is of interest from a psychologic standpoint Soon after the onset of the progressive deafness an otologist was consulted After the usual examination and preliminary series of inflations, many of these patients were told that further treatment would not help them and a certain number were told that they had otosclerosis A few were content and had no further treatments The majority went from doctor to doctor until nearly half had found some one to perform an operation on the nose or throat to help the hearing, while most of these patients had tried some form of quack remedy ranging from osteopathy and chiropractic to roentgen therapy of the pituitary and finger surgery of the eustachian orifice Nearly every one of these 115 patients had the same story to tell During each treatment, whatever its nature, the hearing seemed to be improved, but within a few months it was realized that the hearing was actually no better and, in fact, that the deafness had continued to progress as before An important consideration for the otologist in treating these patients is to appreciate the necessity for early psychologic adjustment and to help these patients make this adjustment Prolonging false hopes by unnecessary treatment and prolonging the stage of psychologic adjustment do not make these people happier

DR W V MULLIN, Cleveland For some years this section has had a committee which has concerned itself with the problems of the hard of hearing I have no criticism of the work of these committees in the past, but I do question the effectiveness of their work The profound impression that Dr Berry's paper has made on every one here today was manifested by the applause he received It occurs to me that if this section wants to do something that would be of inestimable value to the deaf, I would suggest, and if the chairman desires I will put it in the form of a motion, that we make it possible that a large number of copies of these inspiring words of Dr Berry's be printed, so that they may be widely disseminated in leagues for the hard of hearing and may reach deaf people rather than be left buried in the transactions of the section, where they will be available only to the few

DR HARRIS P MOSHER, Boston This will come up in the regular business meeting where ways and means will be carefully considered

DR GORDON BERRY, Worcester, Mass I appreciate the kind reception that has been given this paper My effort has been twofold to crystallize for the otologists their own observations, and, through them, to help their hard of hearing patients into a happier and more hopeful philosophy of life I have tried to show how, in the last analysis, the adjustment must be from within, not from without, and that each individual has the power to attain this adjustment and, through it, serenity for himself and happiness for his friends Through kindly guidance and sympathetic understanding, we as otologists have a unique opportunity to help these hard of hearing, individually and in organized groups into this desired adjustment

The Decomposition of Radium—Radium decomposes into radon Radon, in turn decomposes into an element called radium A and this in turn into radium B, radium C, radium C', radium D radium E and radium F (polonium), which disintegrates into lead the stable end-product of this decay series—Evans R D Radium Poisoning—A Review of Present Knowledge *Am J Pub Health* 23 1017 (Oct) 1933

FUNDAMENTAL DIFFICULTIES IN THE
TREATMENT OF PEPTIC ULCER

WALTER LINCOLN PALMER, MD
CHICAGO

The two chief problems of ulcer therapy are, first, to promote healing of the lesion present and, second, to prevent its recurrence. My purpose in this paper is to emphasize the fact that the fundamental difficulty in accomplishing both of these ends is that of satisfactorily combating the digestive action of the gastric juice over adequate periods of time.

It has been known for years that acid gastric juice is able to kill and digest living tissue. In 1859, Claude Bernard showed that the leg of a living frog is digested when introduced through a fistula into the stomach of a dog. This work has been repeated and extended recently by Dragstedt and his co-workers.¹ It has been found that the concentration of pepsin is of relatively little importance compared with the concentration of acid, that digestion occurs with acid concentrations above 0.1 per cent and that the rate of digestion is almost proportional to the acid content. For some reason as yet unknown the gastric mucosa under normal conditions escapes digestion. Also unexplained is the fact that experimentally produced defects of the gastric mucosa heal in spite of the presence of normal secretion. For a long time this observation threw considerable doubt on the theory that ulcer formation results from the digestive action of the gastric juice.

In the course of years, however, a gradually increasing and now almost conclusive amount of evidence has accumulated to show that acid gastric juice is the *sine qua non* of ulcer. This evidence may be summarized

chloric acid. The literature on this subject has been reviewed elsewhere, but it suffices to state that there has not been reported, up to the present time, any satisfactorily proved case of chronic gastric or duodenal ulcer with complete achlorhydria. When one considers that the incidence of achlorhydria in otherwise normal men and women of all age groups averages about 12 per cent,² this absence of cases of ulcer with achlorhydria becomes of great significance.

Chart 2—Effect of atropine on free acidity. Duodenal ulcer. Half hour titrations. The patient was given 90 cc of milk and cream hourly from 7 a m to 7 p m and 90 cc of water hourly from 7 30 a m to 7 30 p m and half hourly thereafter.

It is also important to recall that the term "peptic ulcer" has arisen from the fact that lesions of this type are found only in those portions of the digestive tract exposed to peptic activity, namely, the lower part of the esophagus, the stomach and the first portion of the duodenum. Operations that result in the drainage of acid gastric juice into the jejunum, ileum or colon may result in ulcer formation at these sites.

One of the most interesting and conclusive proofs of the role of acid is to be found in the ulcers of Meckel's diverticulum, so carefully studied by Aschner and Karelitz,³ Lindau and Wulff,⁴ and others. The ulceration develops in the mucosa of the ileum and is apparently due to acid gastric juice secreted by islands of aberrant gastric mucosa in the diverticulum. Similar lesions have been produced experimentally in the dog by Dragstedt and Matthews⁵ by anastomosing a Pavlov pouch to the end of a loop of small bowel. The acid gastric juice from the pouch drains into the loop of the small bowel and an ulcer results. When the acid is continuously neutralized by alkali, an ulcer does not develop.

The experimental evidence of the direct relationship between acid gastric juice and ulcer formation, resulting in the beautiful work of Dragstedt and Matthews just described, really began in 1923 with the demonstration by Mann and Williamson⁶ that typical chronic peptic ulcer may be regularly produced in the dog by

Chart 1—Free acidity easily controlled with alkali but not controlled with mucin. Duodenal ulcer. Half hour titrations. The patient was given 90 cc of milk and cream hourly from 7 a m to 7 p m and 90 cc of water hourly from 7 30 a m to 7 30 p m and half hourly thereafter. Alkali was administered with the water, mucin with the milk and cream.

under two headings: the clinical and the experimental. It has been well established that ulcer occurs only in those individuals whose stomachs secrete free hydro-

various operations which interfere with the normal neutralization of the gastric acidity by duodenal content. These procedures include transplantation of the common and pancreatic bile ducts into the lower ileum, and drainage of the duodenum into the terminal ileum with anastomosis of the pylorus to the jejunum. Under these conditions, ulcers regularly form in that portion of the bowel into which the acid gastric juice empties. They perforate, bleed and behave in all respects in a fashion similar to peptic ulcer in man. The one factor common to all such successful attempts at experimental ulcer formation is that of interference with the normal neutralization of acid and the subsequent exposure of intestinal mucosa to unneutralized gastric juice.

The available clinical and experimental evidence may thus be seen to give substantial if not conclusive support to the old clinical concept, expressed by Schwarz in 1910 in the dictum "No acid, no ulcer." Acid gastric juice seems to be responsible for the initiation of the lesion for its extension and for its chronicity.

It follows, therefore, that the problem of ulcer therapy is that of protecting the ulcer from the acid. After the lesion has healed, the problem still remains of protecting the mucosa in order that new ulcerations will not develop. The difficulty in accomplishing this is it

Chart 3—Free acidity easily controlled with alkali. Duodenal ulcer half hour titrations. The patient was given 90 cc of milk and cream hourly from 7 a.m. to 7 p.m. and 90 cc of water hourly from 7:30 a.m. to 7:30 p.m. and half hourly thereafter. Alkali was administered with the water.

seems, the fundamental difficulty in ulcer therapy. Theoretically it might be brought about in three ways: first, by coating the surface of the mucosa and of the ulcer with some substance that would protect it from the acid; second, by checking gastric secretion; or, third, by neutralizing the acid after it is secreted. Practically, the desired goal is one difficult to obtain by any of these methods.

My purpose in this study is to present some evidence regarding the ability to control the reaction of the gastric content during the digestive cycle. The method employed has been simply that of aspirating a sample of chyme every thirty minutes from 7 a.m. to 9:30 p.m. and of charting the free acidity. The food intake during this period consisted of 90 cc of equal parts of milk and cream hourly from 7 a.m. to 7 p.m. and 90 cc of water hourly from 7:30 a.m. to 7:30 p.m. and half hourly thereafter. The medication administered is indicated on the charts. They have been chosen as illustrative of the varying conditions encountered and are similar to those previously published.

Chart 1 shows first the curve of the free acidity when milk and cream and water only were taken,

second, the curve when 12 Gm of calcium carbonate and 20 Gm of sodium bicarbonate were taken hourly with the water, third, the result when 10 Gm of commercial mucin was administered with the milk and cream and, fourth, the curve when 10 Gm of purified mucin was given with the hourly milk and cream. The free acidity was well controlled with the alkali but not with the mucin. This chart is quite illustrative of our experience with mucin. It does not control the free

Chart 4—Free acidity not controlled with alkali. Duodenal ulcer half hour titrations. The patient was given 90 cc of milk and cream hourly from 7 a.m. to 7 p.m. and 90 cc of water hourly from 7:30 a.m. to 7:30 p.m. and half hourly thereafter. Alkali was administered with the water.

acidity. The possibility exists, however, that mucin may form a coating over the surface of the ulcer and protect it from the acid, as Fogelson⁸ and Ivy suggest. There is considerable indirect evidence in support of this view, but I have no direct evidence to present.

Chart 2 illustrates the variable effects of atropine. It is well known that atropine in sufficient doses inhibits

Chart 5—Free acidity easily controlled with alkali. Duodenal ulcer half hour titrations. The patient was given 90 cc of milk and cream hourly from 7 a.m. to 7 p.m. and 90 cc of water hourly from 7:30 a.m. to 7:30 p.m. and half hourly thereafter. Alkali was administered with the water. The mixture in this chart in chart 6 and in chart 9 consisted of tribasic calcium phosphate, tribasic sodium phosphate and sodium citrate.

gastric secretion. The question remains, however, whether or not it is possible clinically to prescribe atropine in doses adequate to suppress the secretion of acid. In the first case shown here the administration

of 1 mg of atropine by mouth at four hour intervals had very little effect on the level of the free acidity. In the second case, however, the same dosage resulted in a marked reduction. It is significant that the usual atropine effects, such as dryness of the mouth and visual disturbances, were absent in the first case and quite marked in the second. This observation is quite in accord with the well recognized fact that individual tolerances to atropine vary and that gastric secretion is not affected by atropine unless the other physiologic

trolled by small doses of alkali. Chart 8 shows a case of gastric ulcer recurrent after gastro-enterostomy, in which the free acidity was not completely neutralized even with large doses of alkali.

A further difficulty common to all forms of ulcer therapy, with the possible exception of partial gastrectomy, is that of controlling the night secretion of acid as was first pointed out by Sippy⁹ and as emphasized more recently by Winkelstein¹⁰ and others. Chart 9 illustrates two cases in which the half hour titrations were carried out for a twenty-four hour period. In the first the free acidity was well controlled during the day but became rather high during the early hours of the night. In the second, the acidity was not controlled during the day and became very high during the first part of the night. This continued night secretion may be combated over short periods by the use of atropine and alkali at frequent intervals during the night or by the continuous drip method of Winkelstein,¹⁰ but neither of these methods is feasible for long continued use.

The most satisfactory control of the free acidity is that obtained by the operation of subtotal gastrectomy, which results in the great majority of cases in a complete and permanent anacidity. The incidence of recurrent ulcer after this procedure is lower than that of any other form of therapy. The two chief objections to its general employment, however, are first the relatively high mortality rate even in the hands of the best surgeons and, second, that the occasional recurrences are very serious and can be treated only by further gastric resection.

When one considers the entire subject of ulcer therapy, it is of course obvious that the difficulties vary from case to case. They depend to a great extent on the complications present. In one marked duodenal stenosis may constitute an indication for gastro-enter-

Chart 6—Free acidity poorly controlled with alkali. Duodenal ulcer half hour titrations. The patient was given 90 cc of milk and cream hourly from 7 a m to 7 p m and 90 cc of water hourly from 7 30 a m to 7 30 p m and half hourly thereafter. Alkali was administered with the water.

effects are produced. These are so disagreeable, especially when the mental symptoms develop, that the continued administration of effective doses of atropine is scarcely possible.

The first scientific attempt to control continuously the reaction of the gastric content was made by Sippy⁹ in 1915. Chart 3 illustrates the manner in which this is accomplished. The free acidity is well controlled with moderate doses of alkali.

The not infrequent occurrence of alkalosis with alkali therapy when either calcium carbonate or sodium bicarbonate are given in such large doses has led to the employment of substances less likely to disturb the acid-base balance of the blood. One of these is a mixture of tribasic calcium phosphate, tribasic sodium phosphate and sodium citrate. This neutralizes the gastric free acidity satisfactorily in many instances, as is illustrated in chart 4.

There are numerous patients, however, in whom the administration of alkali even in large doses does not result in complete neutralization of the free acidity, as is shown in charts 5 and 6. These are the cases that are most difficult to treat medically and surgically and are the ones in which recurrent lesions are most frequent.

The effect of gastro-enterostomy on the free acidity is rather variable. In some cases a definite lowering seems to result, whereas in others there is no appreciable effect. Chart 7 illustrates a case in which the free acidity after gastro-enterostomy is somewhat lower than it was prior to the operation and more easily con-

Chart 7—Free acidity before and after gastro-enterostomy. Duodenal ulcer half hour titrations. The patient was given 90 cc of milk and cream hourly from 7 a m to 7 p m and 90 cc of water hourly from 7 30 a m to 7 30 p m and half hourly thereafter. Alkali was administered with the water.

ostomy, in another, a large intractable gastric ulcer or a recurrent jejunal lesion may lead one to recommend a partial gastric resection. But in every instance the one fundamental problem is that of protecting the lesion and the mucosa from the digestive action of the gastric juice.

⁹ Sippy, B. W. Gastric and Duodenal Ulcer. J. A. M. A. 64: 1625 (May 15) 1915. Oxford Loose Leaf Medicine 3: 153. 1923.

¹⁰ Winkelstein, Asher. Proc. Am. Gastro-Enterol. A. 1932.

The extent to which this can be accomplished with mucin or some such protective coating is as yet unknown. A satisfactory method of inhibiting gastric secretion is not yet available. Atropine is of some value in this respect and does have a definite place in ulcer therapy. The antacid regimen of Sippy or one of its various modifications in which different forms of alkali are used in varying amounts accomplishes satisfactory neutralization in many instances and is, on the whole, the most satisfactory form of medical therapy

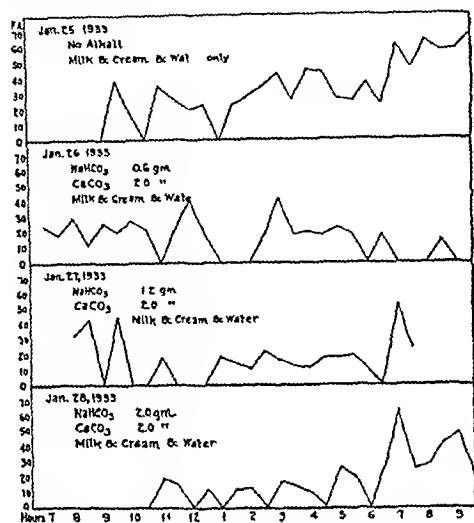

Chart 8—Free acidity not controlled with alkali. Gastric ulcer recurrent after posterior gastro-enterostomy. The patient was given 90 cc of milk and cream hourly from 7 a m to 7 p m and 90 cc of water hourly from 7 30 a m to 7 30 p m and half hourly thereafter. Alkali was administered with the water.

now in use. In many cases, however, it is impossible at the present time to obtain complete neutralization for sufficient periods of time to enable healing to occur, and it is even more impossible to reduce permanently the acidity and thus to prevent recurrence. This group of patients with a very high gastric secretion constitutes the most difficult therapeutic problem and illustrates most forcefully the fact that the fundamental difficulty in ulcer therapy is that of combating the digestive action of the gastric juice.

CONCLUSIONS

- 1 Evidence is presented to show that ulcer formation is dependent on the presence of acid gastric juice.
- 2 The fundamental difficulty in therapy is conceived to be that of protecting the lesion or the cells of the mucosa from the destructive effect of the acid.
- 3 Mucin or some such substance may form a coating over the surface of the ulcer and thereby protect it from the attack of the acid, but satisfactory proof of this has not yet been produced.
- 4 Mucin does not accomplish complete neutralization of the gastric free acidity.
- 5 Atropine, in physiologic doses, decreases gastric secretion, but the attendant atropine effects seriously limit its usefulness.
- 6 Gastro-enterostomy may or may not lower the acidity, but rarely produces complete neutralization.
- 7 Subtotal gastrectomy usually results in complete and permanent anacidity. The objections to its general adoption are the relatively high mortality rate and the gravity of the lesions when they do recur.
- 8 Complete and continuous neutralization may be accomplished in many cases by the hourly milk and

cream and alkali regimen of Sippy. Frequently, however, it seems impossible to obtain satisfactory control of the free acidity even with large doses of alkali. In spite of this fact, conservative medical therapy based on the principle of acid neutralization remains the treatment of choice for uncomplicated peptic ulcer.

950 East Fifty-Ninth Street

ABSTRACT OF DISCUSSION

DR SIDNEY A. PORTIS, Chicago. There is no doubt that the acid secretion is a very important factor, not only in the production but also in the life cycle of a peptic ulcer. I am not convinced that the present method of attack is ideal. Neither am I convinced that surgery should be done for all types of ulcers, but I do firmly believe that large calloused ulcers, ulcers that penetrate and ulcers with marked deformities, as well as ulcers with a recurrent history of bleeding had better not be handled by gastro-enterologists. The sooner such an individual sees a surgeon, the better will be the prognosis. Certainly, in this type of case, gastro-enterostomy has offered but little in addition to what medical management has done. One feels confident that patients who have been subjected to a subtotal gastrectomy, followed by accurate medical management, have been given the best chance to get a more or less complete recovery and to return to their normal place in the economic world. I have never been convinced that complete neutralization of gastric acidity is necessary to promote the healing of an ulcer. My own practice, particularly in the case of a duodenal ulcer, is to lessen the motor drive of the stomach, to keep the pylorus more or less patent, and to devise measures for more rapid and earlier emptying of the stomach. I feel that atropine or its derivatives should not be used to the physiologic limit of checking gastric secretion but should be used only to relieve the associated pylorospasm. In the handling of an ulcer patient, one must recognize the fundamental contributory factors in the production of an ulcer and attempt to remove them.

DR CLARENCE F. G. BROWN, Chicago. Fifteen years ago I was taught that if the acids are controlled the ulcer will heal, and for the last fifteen years I have been trying to control acidity. The difficulty sometimes seems to be that the more the patient is treated the higher the acids become. The remarkable thing is that during that time in many instances, in fact, in most instances, the ulcer is healing. It has been difficult to reconcile the old teaching of Schwartz "the less acid or no acid no ulcers," with the experience at times that "the more acid

Chart 9—Difficulties in day and night control of free acidity. The patient was given 90 cc of milk and cream hourly from 7 a m to 7 p m and 90 cc of water hourly from 7 30 a m to 7 30 p m and half hourly until 9 30 p m. 4 Gm of the mixture was taken with the water.

no ulcers.' If ulcers heal with rising acid there certainly are other defense factors present. This complex might be called a defense mechanism of the stomach. These factors are many, one cannot say it is the hydrochloric acid or it is this or that. First is the ability of the stomach to empty itself, then there is the regurgitation and the modified Boldyreff idea, the chloride metabolism both local and general, the mucous glands and their possible protective secretion and tissue regenerative ability in the particular patient. Everything one puts in the stomach is a secretagogue. Gruel is a secretagogue, so is soda and so

is mucin. Even water is a secretagogue. An attempt must be made to control the acidities as well as possible. The first thing to do is to improve the patient as a whole. If that is done, the acids tend to normalize. The bowel must be rendered normal, that is, functionally normal, and that tends to normalize the acidities. Thirdly, the ulcer must be treated, and, in thinking of the defensive mechanism in the individual case, one must try to choose the treatment which agrees with that particular patient.

DR ROBERT KAPSINOW, Lafayette, La. The title of this paper is characteristic of the experiences of many who attempt to treat peptic ulcer. I should like to change the dictum "No acid, no ulcer" to "No ulcer in the presence of acid if the mucosa is healthy." I have also treated the acidity by chemical neutralization and protected the mucosa with colloids. Some time ago I produced ulcers in healthy dogs with healthy mucosa surgically, and I was surprised to see how rapidly the mucosa would heal in spite of the fact that I introduced more acid into the stomach. I was one of those quoted in the author's paper who deflected bile from the duodenum by a simple experiment connecting the gallbladder with the pelvis of the kidney and ligating the common duct, and in a very large percentage of cases produced peptic ulcers. Later I reconnected the biliary tract and only a certain number of these ulcers were cured. I am not convinced that acidity is the entire picture in controlling the healing of ulcers. I believe that if ulcers are classified according to the anatomic origin, and the patient is treated systemically and his regenerative powers are built up, success will probably result. Those who heard Dr. Levine's paper on the nonspecific treatment of ulcers with Brooks's hemoprotein were surprised at his remarkable results, I am sure. His object was to attempt to build up tissue regeneration and allow the stomach to repair itself locally. It seems as if it might be a useful therapeutic agent to try in those people whose ulcers recur in spite of all forms of therapy.

DR G. A. HENDON, Louisville, Ky. It has always been an accepted fact that any ulcer of any organ of the body, unless it is of syphilitic, tuberculous or cancerous type, will heal if the organ involved can be put at rest for a sufficient length of time. Acting on this principle, I have been able to cure twenty-three ulcers, some of which had histories dating back eleven or twelve years. The case of longest duration dates back four and one-half years and there is no evidence of recurrence. I have been able to put a pound a day for thirty days on patients without any difficulty. I do this by a process that I call venoclysis, a description of which appeared in *THE JOURNAL*, Oct. 18, 1930. With this method I am able to supply nutrition to the system for a period varying from ten to fifteen days with nothing at all entering the stomach except water. The stomach under the conditions apparently goes to sleep, folds up and becomes alkaline, and the ulcer gets well. It is the most startling and the most impressive spectacle that I have seen in medicine, particularly in connection with massive hemorrhages. I control those massive hemorrhages almost instantaneously and without any difficulty. I accomplish this by a method I have developed of supplying nutrition continuously into a vein of the arm or the leg. Fifteen days has been as long a period as was found necessary.

DR SARA M. JORDAN, Boston. I feel, as Dr. Palmer does, that acid is the predominant factor. It may well be associated with the motor drive that Dr. Portis mentioned and the other factors that have been mentioned, but it seemed to me in reviewing a considerable group of duodenal ulcers that the successful cases were those in which good remissions were found. They were those in which the acid decreased and especially those in which the night secretion of acid was found to have decreased during treatment in the hospital. It seems to me that is a very definite and important factor.

DR A. L. LEVIN, New Orleans. Years ago Moynihan asked the question "Why is it that the gastric cell born reared and developed in an acid medium should all of a sudden be afraid of an acid?" I do not believe that hydrochloric acid is the factor which prevents healing of a chronic peptic ulcer. The various methods of treatment to control the gastric acid are probably physiologically not correct. Every human machine

is provided with a mechanism to defend itself against a process of degeneration that might develop during the course of its existence. The aim in the treatment of lesions of the body anywhere should be to increase the power of regeneration and to destroy the destructive agents. I believe that the nonspecific proteins which are coming to the fore in modern medicine are a promising medium to heal peptic ulcers. I have made clear my views in this regard in a paper on this subject presented this morning in the Section on Pathology and Physiology. It is only a question as to what type of nonspecific protein should be selected for that purpose.

DR WALTER L. PALMER, Chicago. The point I hoped to make is that ulcer is an interaction between acid and mucosa. No one knows why the normal stomach is not digested by the gastric juice within it or why ulcers heal in spite of high acid and why some stomachs are perfectly normal and yet have just as high an acidity as is found in ulcer. These are unsolved problems. But there is this definite relationship between ulcer and acid. I agree that the mucosa is diffusely involved, as Konjetzny has shown, but this also is probably due to the action of acid on the mucosa. The problem, then, is Can the mucosa be protected or the acid be done away with?

FETAL MORTALITY IN THE TOXEMIAS OF PREGNANCY

C. H. PECKHAM, M.D.
BALTIMORE

During recent years there has undoubtedly developed an increasing tendency to view the various toxemias of pregnancy with greater concern than was hitherto the rule excepting in the case of eclampsia. In the latter condition the immediate maternal mortality has always been sufficiently high so that all forms of therapy have concerned the mother, and the outcome to the child has received little regard. Such a course of procedure, however, has not pertained to the other toxemias of pregnancy, and it has been a rather general custom to treat such cases by palliative means until the pregnancy reached term or the child attained a definite period of viability. More recently the wisdom of such a procedure has been seriously questioned. It is generally agreed that chronic nephritis is definitely aggravated by pregnancy, the severity of the condition after pregnancy is much advanced over that pertaining before it, and the amount of renal damage suffered is in more or less direct ratio to the duration to which the pregnancy is allowed to continue. Also, there is reason to believe that a considerable number of women suffering from a non-nephritic variety of toxemia, and in whom the pregnancy is allowed to continue, will be found to have a definite chronic nephritis some months after delivery.

These rather latent dangers of the toxemias become evident when follow-up studies are made some months or years after delivery. Thus, in 1931, Stander and I found that in a series of patients with undoubted nephritic toxemia who were restudied from one to ten years after delivery, 42.53 per cent had already died from chronic nephritis. It was also shown that pregnancy subsequent to the diagnosis of nephritis materially shortened the patient's average expectancy of life and hastened the fatal outcome. Moreover, Stout and I found in a series of 515 consecutive patients suffering from the various toxemias of pregnancy,

From the Department of Obstetrics the Johns Hopkins University and Hospital.

Read before the Section on Obstetrics, Gynecology, and Abdominal Surgery at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 15, 1933.

excluding vomiting and eclampsia, that 40 per cent had a definite nephritis, usually arteriosclerotic in type, four or more months after delivery

What, then, is to be one's opinion as to the advisability of allowing a toxemic pregnancy to continue to term or near term? Obviously the only reason for not immediately emptying the uterus is the desire to

TABLE 1—Gross Statistics of Patients in Series

	Number
Patients	499

Total mortality	14.93

obtain a live child. Unfortunately, it often cannot be determined prior to delivery whether a given case of toxemia is nephritic or non-nephritic in character. I believe that the severer the toxemic manifestations, and the earlier in pregnancy they appear, the more probable it is that the case will eventually show chronic renal involvement. It is my aim in this paper to study these various signs and symptoms of toxemia of pregnancy in their relation to fetal mortality and to determine whether or not in the severer forms the outcome for the child counterbalances the increased risk to the mother.

For this purpose I have analyzed the course of 623 consecutive cases of toxemia followed to a termination of the pregnancy in the obstetric service of the Johns Hopkins Hospital from June 1, 1926, to May 31, 1930. Included in this group are twenty-six cases of toxemic vomiting and fifty of eclampsia, and the fetal mortality in these is considered separately. In the remaining patients the outcome to the child is studied from the following points of view: race, age

toxemia, as diagnosed four or more months after delivery. The latter analysis was done because it is my opinion that in many instances of toxemia an accurate diagnosis of the type of condition at hand cannot be made until several months after delivery of the patient.

It will be noted subsequently that in most instances two mortality percentages are listed. One, termed "fetal mortality per cent," is based on the cases in which the pregnancy proceeded to a period of viability for the child. The other, "total mortality per cent," includes also those instances of pregnancy in which toxemia terminated in abortion, either spontaneous or therapeutic. The latter figures seemed worth including since they give, possibly, a truer picture of the actual risk to the fetus in a given pregnancy.

Twenty-six cases of toxemic vomiting, severe enough to warrant hospitalization, were followed to a termination of the pregnancy. Of these, thirteen went to term with one death, giving a fetal mortality percentage of 7.69. However, there were nine instances of spontaneous abortion, two of therapeutic abortion, one hydatidiform mole, and one patient died undelivered.

TABLE 3—Mortality in Terms of Blood Pressure of Patient

	Number of Cases	Fetal Deaths	Abortions	Fetal Mortality per Cent	Total Mortality per Cent
Systolic					
to 140	79	5	2	6.49	8.86
140 to 179	223	29	4	10.03	11.26
180 to 209	116	16	6	14.55	18.97
210	41	8	9	23.00	41.46
Diastolic					
to 99	67	5	1	7.58	8.06
100 to 119	281	35	1	12.50	12.51
120 to 139	129	9	7	7.33	12.40
140	52	9	12	22.50	40.38
Pulse Pressure					
to 39	40	2	1	4.17	0.12
40 to 59	271	28	4	10.40	11.81
60 to 79	166	21	7	13.21	16.87
80	43	7	9	20.59	31.21

Including these early fetal deaths we reach a total mortality percentage of 53.85 for this series. Such a figure is discouraging and might tend to make one less conscientious in attempting to prolong treatment in cases of severe vomiting for the sake of the child.

There are fifty instances of typical eclampsia in the series, with twenty-four fetal deaths, a mortality of 48 per cent. It is interesting to note that thirty-one of the women who recovered returned to the dispensary for reexamination four or more months after delivery. Seventeen of them were normal and in these there had occurred three fetal deaths, or 17.65 per cent mortality. However, fourteen at this late date showed signs of undoubted nephritis and nine had had still-born babies, a mortality percentage of 64.29.

Among the remaining 547 cases there were 18 instances of twins. In order not to complicate fetal mortality figures, these have been omitted from further consideration. Thus, there are 529 pregnancies in 499 patients for subsequent analysis. Table 1 indicates the outcome to the child in this series, and, excluding vomiting and eclampsia, one finds a gross fetal mortality of 11.42 per cent and a gross total mortality of 14.93 per cent. It may be noted that the latter figure compares well with the one of 15.84 per cent obtained by Stander for a similar series of cases.

In table 2 is depicted the effect of race, age and parity on fetal mortality. The higher figures obtaining among the Negroes were to be expected, and the difference observed would probably be paralleled in a normal series of cases. It will be noted that both fetal and

and parity of the mother, blood pressure, systolic, diastolic and pulse, albumin and casts in the urine, the amount of edema, the nonprotein nitrogen, uric acid, and carbon dioxide combining power of the blood, the duration of pregnancy when signs or symptoms of toxemia first became manifest and the length of time from the appearance of these phenomena to delivery, and, finally, the fetal mortality in the various types of

total mortality percentages rose rapidly with increasing age and parity. Since nephritis is found much more frequently in the higher age groups and among the greater parous and since extremely high mortality rates are observed in these groups even when the pregnancy is allowed to progress to a period of viability for the

child, it would seem reasonable to be much more inclined to interrupt the pregnancy in patients of this type than in the younger woman and the one with fewer living offspring.

Table 3 indicates the marked correlation between fetal mortality and increasing blood pressure. It might be stated that the figures given represent the highest point of pressure reached prior to delivery. With marked elevation, i. e., systolic pressure of 210 mm or above and diastolic of 140 mm and above the fetal mortality after viability reaches 25 and 22.5 per cent, respectively, and when pregnancies terminating in abortion are included the total mortality becomes over 40 per cent.

Mortality rates in terms of albumin and casts in the urine and the amount of edema of the patient are depicted in table 4. An increased rate is shown to occur with marked albuminuria or when casts were found on examination of catheterized specimens of urine. The amount of edema was recorded in terms of clinical impression as to degree, and when the edema became moderate or marked the fetal mortality rose to a figure almost twice that observed when no or very slight pitting was to be elicited.

Table 5 is included, since it would seem to indicate that in patients with marked deviation from normal in the chemistry of the blood in terms of nonprotein

nitrogen, uric acid and carbon dioxide combining power, there seems to be a definite increase in fetal and total mortality percentages.

From the foregoing discussion it would seem evident that in cases of nonconvulsive toxemia in which the pregnancy was allowed to progress to a period of theoretical viability for the child, fetal mortality increased directly and definitely in proportion to the severity of the toxemic process. Also, it might well be inferred that in a toxemia severe enough to cause some concern for the mother the result to the child is sufficiently hazardous so that temporizing with the patient for the sake of the offspring is not justifiable.

In table 6 are included only those patients in whom the duration of pregnancy at the time of first appearance of toxemic signs was definitely known from dispensary records. In other words, all these patients

TABLE 6—Mortality in Terms of Period of Pregnancy at Time of Appearance of Signs of Toxemia and Duration of Pregnancy Following the Appearance

8 months and over	9	6	66.67

were normal when first seen and the toxemias developed while they were under observation. I believe that over 90 per cent of toxemias manifesting themselves prior to the seventh lunar month are nephritic in origin. It will be seen that the fetal mortality in patients who developed the toxemia during the last month of pregnancy was excellent, only 2.84 per cent. However, a steady increase obtained with each month of earlier development. In two fifths of the women in whom the toxemic process developed prior to the seventh month but carried to a period of theoretical viability, the child was either stillborn or died in the first two weeks of life. Conversely, the highest mortality figures are found in the patients allowed to progress the longest time between development of toxemic signs and delivery of the child.

Preeclampsia	1	8	1	16.00	17.00
Nephritis	13	26	1	19.67	23.43
Unclassified	7	0	0		

These figures would seem to permit two general statements. The outcome to the child renders dubious the wisdom of attempting to carry a patient in whom toxemia appears before the child is viable. Moreover, with the child definitely viable and a toxemia appearing its best chance seems to lie in reasonably prompt induction of labor.

The fetal and the total pregnancy mortality are portrayed in table 7. It will be noted that the fetal mortality for the general clinic population was about 5.5 per cent. The outlook for the child in cases of low reserve kidney was rather favorable, and a total mortality percentage of 9.46 was obtained. However, preeclampsia denotes a much more unfavorable prognosis (17.66 per cent) and in this series more than a fourth of the pregnancies associated with chronic nephritis terminated unfavorably to the child. The rates in vomiting, and eclampsia have already been commented on.

Two more items affecting the prognosis to the child might also be considered. The mean weight of babies born to women with low reserve kidney was essentially the same as with normal patients. However, in the preeclamptic, eclamptic and nephritic groups the weights, although essentially equal among the three types of cases, averaged from 11 to 12 ounces (310 to 340 Gm.) below the general clinic population. Also, the percentage of women able to nurse their babies successfully was far lower in these three groups.

COMMENT

The present study was undertaken to determine the fetal mortality in a series of consecutive deliveries of patients suffering from the various toxemias of pregnancy and also to correlate such mortality rates with the clinical course of the toxemias. If possible, it was desired to answer the questions as to whether the results to the child were good enough to warrant temporizing with the patient in the severer cases, and also whether or not the increased risk to the mother attendant on such temporization was counterbalanced by a favorable prognosis for the child. The mortality rates given are two: fetal mortality in terms of deaths of viable infants, and total mortality, which also includes pregnancies terminating spontaneously or by artificial means before a period of viability for the child is reached.

The prognosis for the child was good in cases of toxemic vomiting, provided the pregnancy progressed to a period of viability for the child. However, in about half of the cases in this series the pregnancy terminated in abortion, usually spontaneous, and the total mortality percentage found was 53.85. The fetal mortality in eclampsia was 48 per cent.

In the remaining patients the toxemia was analyzed from various clinical standpoints and correlations were made with fetal mortality. Higher mortality rates obtained in the Negro than in the white race. Advancing age and parity of the patient were attended with increasing risk to the child. Definite correlation was obtained between the mortality and the rising blood pressure (systolic, diastolic and pulse), the increasing albuminuria, the presence of casts in the urine and the amount of edema. In patients with marked deviation from the normal in the chemistry of the blood, the outlook for the child became poor.

The later in pregnancy the toxemic signs developed, the better was the prognosis for the child. Conversely, in cases in which such signs developed before the child was viable the chances of its survival became extremely poor. It is my opinion that the great majority of such cases are nephritic in origin. Also, the risk to the fetus increased directly with the length of time elapsing between the onset of the toxemia and delivery.

A high fetal mortality rate obtained with all the types of toxemia of pregnancy. The outlook of the child in cases of low reserve kidney, however, was not bad. It

became more dubious in preeclampsia, and in chronic nephritis, including the mildest types, a total mortality percentage of over 25 prevailed.

From the foregoing discussion it would seem that the following statements can be safely made. In the milder cases of toxemia the pregnancy may be carried until the child is undoubtedly viable, this carries with it a good prognosis. Once such a period has been reached and the toxemia persists, it would seem preferable for both patient and fetus to induce labor by conservative means.

In the cases with severer toxemic manifestations it seems that the outlook for the child is so poor that it should have little effect on the treatment of the patient, all efforts being made to deal with the condition of the mother. The immediate mortality to the patient, should eclampsia eventuate, is still so high and the later effects of nephritis so severe that only in the very exceptional case and after detailed explanation to the patient and her family of the risks involved is one justified in prolonging pregnancy in cases of severe toxemia for the sake of a child whose chances of survival are relatively poor.

ABSTRACT OF DISCUSSION

DR JOHN W. HARRIS, Madison, Wis. Dr. Peckham's paper is added evidence of a marked change in thought concerning the ultimate prognosis in the late toxemias of pregnancy. Until the past few years it was generally thought that, save in the frankly nephritic toxemias, recovery from the acute attack left the patient uninjured so far as renal sufficiency was concerned. In fact, some have stated that such patients were even less likely to suffer from similar complications in subsequent pregnancies. In the past few years, follow-up studies of patients suffering from the late toxemias of pregnancy have shown that this degree of optimism is not justified. Several years ago I found that more than half of the patients who had been previously diagnosed as preeclamptic showed unmistakable signs of chronic nephritis one year subsequent to delivery. Some of the studies by Dr. Peckham and by others have resulted in similar conclusions. Dr. Peckham contributes a somewhat gloomy prognosis so far as the baby is concerned. It would seem that, unless the toxemia responds promptly to ameliorative measures, it is hardly justifiable from the standpoint of the mother and the baby to delay interruption of pregnancy.

DR FRED L. ADAIR, Chicago. I am glad that Dr. Peckham presented this topic from the aspect of the fetus. One could accept the tenet that there is never anything to gain for the mother with toxemia of pregnancy from prolonging the pregnancy. The only reason for temporizing in these cases has been the possible benefit to the fetus. I have long felt that there is no use in temporizing with a toxemic case when the fetus is previsible unless it is approximately viable, nor is there any use temporizing with a case of toxemia after the fetus has once reached the period of viability. Therefore I have felt that the only type of case of toxemia in which there was justification for temporizing from the standpoint of benefit to the fetus was when the period of gestation was on the borderline between previsibility and viability. In some of those cases the period of gestation can be carried along a week or so, so that there may be a fair chance of obtaining a viable fetus. A few figures from a series of about a thousand autopsies that were carried on while I was in Minneapolis will give some idea of the number of fetuses which die as the result of toxemia in the mother. There were 114 nonconvulsive cases of toxemia in which the fetus died. In other words, over 10 per cent of the fetal deaths in the series resulted in cases of nonconvulsive toxemia. In convulsive cases there was a somewhat smaller percentage, approximately 30, making in all, however, a figure of 144 cases out of something over a thousand fetal autopsies. So far as the causes of fetal death are concerned, they are quite varied. In the nonconvulsive cases, respiratory complications were found responsible with pulmonary atelectasis in 63 of the cases, suffocation in 17, aspiration in 11 and birth trauma in 32 of

the instances, placental degeneration was supposed to have accounted for 24 of the deaths, and 29 were attributed to the toxemia. In the convulsive cases the pathologic examination justified death as due to respiratory difficulties, with pulmonary atelectasis in 11 and suffocation in 6, birth trauma was the major cause of death in these cases, accounting for 15. I will not enumerate the causes of lesser frequency.

DR JOSEPH B. DE LEE, Chicago. It is generally known that the mortality of babies in cases of toxemia and particularly in cases of chronic nephritis in pregnancy is very high. It is also known that women with acute toxemia are likely to have damage to their kidneys later on, which will shorten their lives. It is particularly well known that women who have chronic nephritis in pregnancy have the damage to their kidneys exaggerated. In view of those facts it is important to realize that such a woman having a baby places a high valuation on that one baby's life. She ought not to have any more babies, certainly not more than two. Therefore the method of delivery selected in the cases of toxemia and chronic nephritis should be one that offers the least possible damage to the baby. Babies of women that are toxemic are vulnerable, their brains are soft, their blood vessels are fragile, and they are more likely to suffer damage during the natural processes of delivery. In view of these facts it is very important to consider the method of delivery, the method of inducing labor, in cases of chronic nephritis during pregnancy. I would like to suggest that the low cervical cesarean section under local anesthesia, with an emphasis on the local anesthesia, be very very thoroughly considered in the delivery of premature babies in toxemic women and chronic nephritic women.

DR A. C. POSNER, New York. The obstetric service of the Harlem Hospital, New York, has made a special study in an attempt to reduce the fetal mortality in the toxemias of pregnancy for the five years beginning Jan. 1, 1928, and ending Dec. 31, 1932. These statistics are based on 9,068 consecutive maternal admissions. The mortalities are uncorrected. In forty-two cases of pernicious vomiting of pregnancy the fetal mortality was 38.09 per cent. The difficulty of classifying toxemias is apparent. We do not classify chronic nephritis as a toxemia but as a very serious complication of pregnancy. The fetal mortality in thirty-five cases of chronic nephritis was 20 per cent. The fetal mortality in 153 cases of increased blood pressure without any other symptoms was 9.80 per cent. The neonatal mortality for this group was 4.57 per cent. In the severe toxemias of pregnancy, such as pre-eclampsia, the fetal mortality has been reduced from 40 per cent in 1928 to 5.55 per cent in 1932. The fetal mortality for 186 cases of this group was 13.9 per cent. The neonatal mortality has been reduced from 18.5 per cent in 1928 to 4.42 per cent in 1932. The average neonatal mortality for these 186 cases was 7.52 per cent. I disagree with Dr. Peckham on one point. I feel that, if he will compare an equal number of toxic Negro patients who have had prenatal care and have a negative Wassermann reaction with a similar white group, the fetal mortality will be of equal or lesser incidence among the Negroes. The reduction of the fetal mortality in toxemias has been accomplished in three ways: 1. Increased attendance at the clinic. This has followed decreased employment among women. In 122 cases of the pre-eclamptic group in which prenatal care was given, the fetal mortality was 9.83 per cent. In 64 cases of this group in which prenatal care was not given, the fetal mortality was 25 per cent. 2. Establishment of a special toxemia clinic. Here each case is studied in association with the department of metabolism. 3. Induction of premature labor. All patients with toxic symptoms or with systolic blood pressures of 140 or more are hospitalized, treatment is immediately instituted and if the child is viable and no improvement is noted in forty-eight hours, induction of labor is instituted by a modified Watson method. If this is unsuccessful, the membranes are ruptured and induction is repeated. Successful chemical induction has been accomplished in over 85 per cent of these cases. Early recognition and treatment of toxemia have made eclampsia a very rare disease among clinic patients. In 1928 there were 23 cases. In 1932 there were 9. The incidence was 1 to 78 admissions in 1928. In 1932 it had decreased to 1 in 200 admissions. The fetal mortality has been reduced from 46 per cent in 1928 to 11 per cent in 1932. The fetal mortality of 65 cases of eclampsia during these five years was 35.38 per cent.

DR C. H. PECKHAM, Baltimore. I would emphasize once more the difficulties attendant on the proper diagnosis of a given toxemia of pregnancy. It is the policy at the Hopkins Clinic in cases of undoubted nephritis not to allow the pregnancy to continue. However, we find more and more that some of our clinical impressions as to a given toxemia during pregnancy are wrong. We can diagnose a far-advanced case of chronic nephritis or eclampsia, but in the milder toxemias particularly if the patient appears only subsequent to the seventh month of her pregnancy, it seems almost impossible to tell whether she has a nephritic or a non-nephritic toxemia, and hence our treatment, so far as the child is concerned, becomes a very difficult problem.

THE VALUE OF PSYCHOANALYSIS AS A THERAPEUTIC PROCEDURE

LEO KESSEL, MD

AND

HAROLD THOMAS HYMAN, MD

NEW YORK

For the past twelve years we have referred various of our patients to accredited psychoanalysts. Our experiences form the basis of this report.

The psychoanalytic movement has had a widespread influence on human thought and conduct. Not only have Freud's monumental contributions influenced modern medicine and related sciences such as psychology, sociology and criminology but they have also been reflected in the seven arts. The internist has a pragmatic interest in psychoanalysis apart from the point of view of general culture. He seeks to define the indications for and the limitations and results of this new therapeutic procedure.

Before detailing our data, terms must be defined. One must state (a) the qualifications for a psychoanalyst, (b) a conception of what constitutes an analysis, and (c) a description of the type of clinical material referable to the psychoanalyst for the analysis.

THE PSYCHOANALYST—HIS TRAINING AND QUALIFICATIONS

It is our opinion that the psychoanalyst should be a licensed physician. The additional qualifications laid down by such bodies as the New York Psychoanalytic Society are highly desirable if not mandatory. The psychoanalyst should have had a general internship, he himself should have submitted to a psychoanalysis by a previously accredited psychoanalyst, and, finally, he should have performed, under the guidance of a society such as the New York Psychoanalytic Society, at least two probatory analyses to establish his fitness to go on in his special field.

Beyond these definite stipulations and because of the peculiar nature of the field the internist who refers patients to a psychoanalyst should choose an individual who is himself adjusted to his environment and whose character, habits and mode of life are impeccable.

THE UNQUALIFIED PSEUDO-ANALYST

The lay analyst and those accredited physicians who, without special training, presume to practice analysis have been responsible for many great tragedies. These instances should not be cited to the detriment of the psychoanalytic movement as a whole. Such people and certain of the literary intelligentsia have given wide spread circulation to practices and thoughts that are not only not approved of but actually frowned on by the accredited psychoanalyst. By all odds the most

dangerous enemy of the psychoanalytic movement is not the outspoken critic but rather this fringe of borderline enthusiasts and opportunists. It would be a grievous error if the internist were to condemn the method of psychoanalysis and its reputable practitioners for the sins committed by the counterfeiters.

THE PRACTICE OF PSYCHOANALYSIS

In our completed cases the psychoanalyst has required the attendance of the patient for hourly visits from three to five times a week over a period of time extending from six to twenty-four months and usually averaging sixteen months. A complete psychoanalysis is consequently an exceedingly time consuming procedure.

It is the practice of most psychoanalysts to require that the patient make a significant economic sacrifice. As this constitutes an important practical limitation of the method, it will be necessary, unfortunately, to go further into the economics of psychoanalysis.

The psychoanalyst must undergo long, arduous and difficult training, and since he can handle only between twelve and twenty-five patients annually, he must collect a rather substantial fee from each of his patients. Hence, the cost of an analysis far exceeds that of a major surgical procedure, and from a purely economic standpoint it is almost equivalent to a period of hospitalization. Very rarely, in our experience, do analysts take on free patients, and very rarely do the free patients, for whatever reason, complete the analysis. In such instances the patients usually complain of lack of interest on the part of the analyst, and the analyst on his side explains that these patients who make no economic sacrifice are less cooperative than those who do make an economic sacrifice. We have never been particularly impressed with the latter explanation. To an exceedingly wealthy patient the fee for the analysis is not an economic sacrifice, and it has been our experience that in those instances both the analyst and the patient persist quite well with the analysis. In our wide hospital and dispensary experience we have never seen a "free" patient completely analyzed, and certainly this cannot be for want of material.

The economic aspects of psychoanalysis are therefore of considerable importance. It is one therapeutic procedure that is directly dependent on the patient's financial status, and this sharply limits the applicability of the procedure. This is not so much said in criticism of the individuals who practice psychoanalysis as it is a statement of fact.

THE CHOICE OF CLINICAL MATERIAL FOR PSYCHOANALYSIS

In our practice, clinical material available for analytic treatment may be subdivided into four groups.

GROUP 1—Patients suffering from frank psychoses such as schizophrenia, manic depressive insanity and the symptomatic psychoses are promptly referred to the analyst who shows an increasing disposition to reject them for analytic treatment. That this point of view is in accordance with results is evidenced by the fact that, in this group in which the need is greatest, we did not encounter a single satisfactory therapeutic result. The conscientious analyst will accept for therapy only those patients in whom the diagnosis of the frank psychosis is either questionable or whose condition is not far advanced (early schizoid or mild manic depressive patients) not so much in the hope of effecting a cure as of arresting the development of symptoms.

GROUP 2—Patients with behavior problems and maladjustments.

GROUP 3—Patients with simple neuroses and psychoneuroses, such as the various anxiety and compulsion states.

GROUP 4—Patients with visceral symptoms of a functional nature (neurosis actuelle, conversion hysteria, autonomic imbalance).

In the latter three groups the vast majority of the patients are ordinarily handled by the internist. Frequently reassurance that there is no organic disease or a common sense and sympathetic approach to a social problem will go a long way toward the alleviation of symptoms. However, there will always remain a certain number of patients who are resistant to this method of treatment and who, sooner or later, become the plague of the conscientious practitioner. As a general rule, these patients run the whole gamut of therapy both within and without the medical profession. They are usually "cured" recurrently by whatever therapeutic measure or charlatanry happens to be in vogue. Such patients will not realize that their "cure," by whatever method, is always the result of suggestion, and almost invariably, like the proverbial bad penny, they turn up again with their old symptoms or some new equivalent. Frequently these symptoms may actually be incapacitating and always they are exceedingly unpleasant both to the patient and to his medical attendant. Contrary to our practice of promptly referring the true psychotic patients to the analyst, we do not refer patients in the latter groups until we are driven to that procedure by a process of exclusion. In consequence, a result in the latter three groups is a commendable and specific triumph for the analytic method. Analysts who have not had clinical experience must also realize that in these groups there will be obtained a great many successful results which might have been procured by less arduous and less expensive therapy.

THE RESULTS OF PSYCHOANALYSIS

Thirty-three of our patients submitted to a more or less complete analysis, according to the limitations that have been laid down. This does not include our experience with those of our patients who have visited lay analysts or any of the group of charlatans or opportunists within or without the medical profession who, without any qualifications, practice what they call "psychoanalysis."

EVALUATION OF RESULTS

We regard as a specific and successful result the patient who, as a result of his character portrayal, has so rebuilt his personality as to be able to live in harmony in his peculiar and particular surroundings. We regard the result as specific if it could have been obtained in no manner other than by psychoanalysis. We regard the analysis as unsuccessful if the patient continued to have his symptoms after the analysis, if the patient discontinued the analysis, or if the patient was compelled to alter his way of life as a confession of an inability to make an adjustment. We regard as good but nonspecific results those which were obtained when, in addition to the analysis, the patient's way of life was altered in a none too radical way.

1 Bad Results (sixteen cases, 49 per cent) —Suicide (one, 3 per cent). One patient undoubtedly a manic-depressive, committed suicide in the course of his analysis. He had been under analytic treatment for a considerable time by an accredited analyst.

Commitment (six cases, 18.5 per cent). Six patients at one time or another were committed to psychiatric institutions. They consequently either had or developed

true psychoses. Two of these patients had schizophrenia, three had manic depressive insanity and one, unclassified by the analyst, in our opinion, was a schizophrenic.

Failures (six cases, 18.5 per cent). Six cases were definite and complete failures. One of the patients was an intelligent young man who spent eighteen months with an analyst and still presents his anxiety symptoms. A group of three middle aged men, with anxiety symptoms and hypochondriasis, could not be satisfactorily analyzed and discontinued treatment. The fifth patient was an alcoholic addict who continues to be an alcoholic addict. The sixth was a young woman with an anxiety state whose life was almost completely wrecked, probably because of a clumsy analysis. In the last instance, the failure is a personal criticism of the physician rather than a failure of the method.

Change in Marital Status (three cases, 9 per cent). Three of the patients, including one couple, were divorced. As the reason for undergoing analysis by all three patients was to adapt themselves to a situation, we regard the divorce as evidence of failure of the method. In one instance, a woman was married to an impotent male. Her analysis had for its purpose an attempt to adjust herself to this situation and to preserve her home. The fact that she was divorced and that since she has remarried her symptoms have disappeared we regard as a failure of the method, for her analysis was frankly undertaken for the purpose of maintaining her marital status. The other two patients were a couple who were also maladjusted. Since their divorce they have discontinued analysis. The husband became symptom free immediately after the decision for a divorce was made. The wife, who is a constitutional inferior, retains her symptoms. The acceptance of these patients by the analyst, who clearly understood the reason for the analysis, makes necessary the inclusion of these three patients as bad results.

2 Good Results with Qualifications (four cases, 12 per cent).—In four instances patients were relieved of symptoms by analysis plus sexual liberation. Three of these four were women who had symptoms quite obviously due to sex starvation and the resultant conflict between their biologic urge and the reaction of their conscience. Either associated with or as a result of their analysis, all four of these patients indulged in extramarital intercourse, and it is our opinion that the relief of symptoms was due as much to the change in their way of life as to any specific analytic result.

In justice to the psychoanalyst it should be stated that in no instance did the psychoanalyst suggest or urge the termination of the period of continence. These patients experienced a change in their standards which permitted them to indulge in sexual intercourse without suffering so intensely from the pangs of conscience. Whether this change in the moral standards and the liberation of the conscience can be regarded favorably or unfavorably by those of us who practice internal medicine is distinctly a moot question. Certain it is that no physician, whether internist or psychoanalyst, should approve of or sanction extramarital sexual intercourse or, above all, urge his patient to engage in it. One need only point out the definite and tangible dangers of infection and impregnation, to say nothing of the social and moral consequences. This statement should not be interpreted to mean that the physician presumes to sit in judgment on the customs and morals of his patient. Naturally, if individuals elect to philander, that is wholly their own business,

and it is as presumptuous for us to criticize alleged moral turpitude as it is for us to approve of promiscuity. But to return to the patients previously referred to while from a medical standpoint their symptoms were relieved, it is impossible under the circumstances to classify them as therapeutic triumphs of a specific method.

3 Satisfactory Specific Results (thirteen cases, 39 per cent).—**Specific Cures (five cases, 15 per cent).** Five patients were specifically cured of their symptoms by the analysis. Each of these patients was below the age of 30, all were distinctly of the intellectual class, including two lawyers, a musician and a teacher. There were three men and two women in this group. One of the men had actively practiced a sex perversion and his visceral symptoms were due to a conflict over this matter. He was successfully analyzed and cured. He has since married, has children and has been successful in his profession. We feel sure that this man was saved from an inferno and that he could not have been saved by any other method. The two young women had symptoms dating back to maternal conflicts. The one was unable to permit herself to marry as the result of her neurosis and had broken several engagements. The analysis was successful. Her outlook was completely changed, she married, has two children and has accommodated herself well to a number of difficulties. The other young woman has overcome impediments that were obstructing her musical career. She is now not only successful in her profession but is happily married as well. Two young men in the group with anxiety and conversion symptoms are now successful and happy, both in their homes and in their professions.

It is our belief that in these five instances the results were specific and gratifying beyond measure that happiness, usefulness and success were substituted for their opposites, and that the results were attributable to the analysis and could have been obtained in no other way. It is worth while to dwell on certain striking similarities in this group of five who were successfully analyzed. Each of these patients was under 30, each was of the intellectual class, three of the five were the children of wealthy parents who were able to finance the analysis. In only one instance did the patient, by an economic sacrifice pay for his own analysis. In the fifth instance the analysis was financed by a parent in medium circumstances, who made a great sacrifice that the analysis might be consummated.

Good Results (five cases, 15 per cent). Five patients were helped but not wholly relieved of their symptoms. In this group of five, both the patients and the analysts were a great deal more favorably impressed with the results than were we. Our modified enthusiasm, in two instances, was due to the fact that the patients are still unstable but so situated in life that they have been subjected to no stress or strain. While these two patients, both with anxiety states, are at present symptom free, we question their ability to stand up under provocation. A third member of this group was a young physician who was undoubtedly helped but who still presents symptoms of his neurosis at times. A fourth patient with an anxiety hysteria under treatment for four years is better but still presents symptoms. The fifth patient is a young man with a sexual perversion who has been treated with partial success. The four lay patients were distinctly of the wealthy class, the cost of the analysis being defrayed without any great economic strain. In the case of the

physician, no fee was paid, though it has been our experience that the usual courtesies are rarely extended to colleagues by psychoanalysts

Behavior Problems (three cases, 9 per cent) Three adolescent patients presented simple behavior problems that were relieved by an analyst without the adoption of a formal psychoanalysis. While these results are good, they are definitely not specific, and it was our feeling that any simple advice would have been equally successful

SUMMARY

Of our thirty-three cases we classify sixteen, or almost half, as failures. This group includes all the true psychotic patients and all the patients beyond the age of 40 at the time of their analysis

Seventeen of the patients, or slightly over 50 per cent, were helped. In five instances, or 15 per cent, it is no exaggeration to say that the cure was specific. In the fifteen remaining cases the results were good but not startling, and at times the result was not specific but due to the modified circumstances, which have already been elaborated

THE LIMITATIONS OF PSYCHOANALYSIS

Our experience may permit us several generalities concerning the limitations of psychoanalysis. At the present time its practice is sharply limited to a small group of adequately trained physicians who cannot possibly handle more than a numerically inconsequential number of patients annually. A second group of limitations with regard to the patient may be subdivided into those relating to the psychiatric status and those relative to the patient's circumstances in life. With reference to the psychiatric status, the true psychoses, and drug addictions, including alcoholism, where the need is greatest, have the least expectation of assistance. The conditions which have responded favorably, in our experience, include the less ominous syndromes such as the anxiety or compulsion neuroses, the simple behavior problems, and conversion hysteria. It must be emphasized again that in the latter conditions the majority will usually yield to simple reassurance or suggestion of any type, and that only rarely, when the symptoms are persistent or debilitating, is the need for analytic therapy justified

Finally, circumstances other than psychiatric status limits the usefulness of this mode of therapy. Favorable results at the present time apparently cannot be obtained in patients beyond the age of 40. The candidate for therapy must also be in the upper ranges with regard to income so as to stand the expense of a form of therapy which requires attendance from three to six hours a week for well over a year at a fee which is rarely less than \$3 an hour and frequently exceeds \$10 an hour. Again, the patient must be the possessor of a plastic and trained intelligence, for our experience has been that as a general rule the patients are recruited from the professions or the arts and that the average man in the street is wholly unable to grasp or utilize this form of therapy. Despite our receptive attitude toward psychoanalysis as a form of therapy in twelve years we have seen only a handful of patients who have benefited from their experiences

THE HOPE OF PSYCHOANALYSIS

Despite the narrow therapeutic range and the limitations restrictions and criticisms of the analytic method and its practitioners, it is our belief that the freudian

school offers the only intelligent approach toward the successful management of many psychiatric problems. In a broader sense, the newer teachings have widely influenced one's manner of thinking and one's approach to many of the problems that one meets in everyday practice

It is in dealing with the individual patient that disappointment is so keen and criticism so often in order. The support of the movement as a whole and the analyst as an individual has come for the most part from the public and a few enlightened internists, such as the lamented senior author.¹ Medical school faculties and neurologists, in particular, many of the larger hospitals and medical centers have been and in many instances still are openly hostile to psychoanalysis. If this report tends to crystallize thought and render analysts and their critics more tolerant to one another, it will have served its purpose well

POCKET-FLAP SCLERECTO-IRIDODIALYSIS IN GLAUCOMA

CHARLES NELSON SPRATT, M.D.

MINNEAPOLIS

In 1912, I began to do the trephine operation. Since 1925, I¹ have employed a pocket-flap in all operations for cataract or glaucoma. In many of the latter operations, the iris inclusion method was used with sclerectomy. The appearance of the eye with a bleb of subconjunctival pigmentation due to the included iris is not cosmetically desirable, and there is danger of irritation from the incarcerated iris. A case in which panophthalmitis occurred owing to a late infection and the return of pain and tension in several other eyes following iris inclusion led me to adopt a suggestion by Herbert,² namely, an iridodialysis. However, instead of cutting the sphincter as he suggests and pulling the tongues of the iris into the angles of the wound, I have combined iridodialysis with a Lagrange sclerectomy and a pocket-flap. In 1894, de Wecker³ suggested sclerotomy with iridodialysis instead of iridectomy. He seized the iris with forceps and dragged it toward the pupil, thus separating it from the attachment

In the acute form of glaucoma, sclerecto-iridodialysis accomplishes all that simple iridectomy does. It frees the angle of the iris and thus affords drainage into the canal of Schlemm. In the chronic form of glaucoma, if Elliot's trephining or a Lagrange sclerectomy gives relief, this method offers the same drainage. A round pupil is secured, and the patient is not annoyed by excessive glare. Miotics may be used, as the sphincter of the iris is not injured. The conjunctival pocket-flap is thick, and there is less possibility of fistula and late infection

OPERATION

Six grains (0.4 Gm) of sodium amytal or 10 grains (0.65 Gm) of barbitol is given the night before the operation, and the dose is repeated two hours before the operation if necessary. The pupil is contracted

Fig. 1—A deep pocket of conjunctiva is formed, a sclerotomy after the method of Lagrange is done, and the iris is grasped with forceps and is torn loose from its attachment to the ciliary body.

with pilocarpine. Anesthesia is secured by the instillation of 4 per cent cocaine into the eye, four times at four minute intervals. A subconjunctival injection of 1 per cent procaine hydrochloride is made over the superior rectus. In unruly patients, the injection into the lids is made after the method of Van Lint. In inflamed eyes, a hypodermic injection of morphine and scopolamine, or ether, or deep orbital injections,

Fig. 2—Cross section showing the wedge of sclera removed, no stump of iris remains to block the wound.

as suggested by Halstead and reported by Hall⁴ in 1884, may be employed. This latter procedure lowers the ocular tension, especially if the epinephrine, in a dilution of 1:1,000, is added. One cubic centimeter of 2 per cent procaine hydrochloride, with from 3 to 4 drops of epinephrine in a dilution of 1:1,000, is used. The conjunctival sac is thoroughly flushed with

from 1 to 3 cc of hexylresorcinol solution S. T. 37 c metaplen, in a dilution of 1:1,000. If the eye is hard, a posterior sclerotomy is done to relieve the tension and give greater depth to the anterior chamber. The insertion of a suture in the superior rectus muscle helps to maintain fixation of the eye. It should be used when the patient is unable to rotate or hold the eye steady. A horizontal incision 1.5 cm long is made in the conjunctiva 10 mm above the limbus. A thick flap (fig. 1a), which includes the conjunctiva and the subconjunctival tissue, is dissected to the limbus with scissors. A small scalpel is used to separate the fibers of the conjunctiva from the limbus, the cornea is split for from 0.5 to 1 mm (fig. 1b). A conjunctival pocket is thus formed so that the incision is made in a clean field. A mattress suture of 000 black silk on a fine, full curve needle is placed in the edges of the conjunctiva, and the large loops are drawn to the side so that they will not be cut by the knife.

The conjunctival flap is held down over the cornea by blunt forceps so as to obtain fixation of the globe. A Graefe knife, 15 mm in width with a long slender point, is introduced from 1 to 1.5 mm back of the scleral margin, so as just to enter the anterior chamber, and the counter-puncture is made at a corresponding point opposite. This incision is made as far back as possible. Since the incision is confined to the angle

Fig. 3—Stereoscopic photograph of an eye showing round central pupil and separation of the iris from its attachment at the base.

of the anterior chamber, there is no danger of injury to the lens, such as may occur when a keratome is used. The edge of the knife is turned backward so as to make a thick tongue of sclera 3 mm long (fig. 1c). The length of the limbal incision is approximately 4 or 5 mm. The wedge of the sclera is removed with curved scissors, as in the Lagrange operation (fig. 1d). The conjunctival flap is next held up so that the iris may be distinctly seen. This is grasped at the root with delicate curved iris forceps having teeth on the convex side (Foerster model). The iris is pushed gently toward the center of the pupil, and separation of the root from its attachment to the ciliary body (iridodialysis) follows (fig. 1e). The suture is drawn tight and the wound closed (fig. 1f). The patient is allowed to sit up in bed, the eye operated on being bandaged. The next morning the eye is gently massaged, this should be repeated daily. Should there be pain, atropine is instilled.

It will be noted that the flap produced (the Husum flap) is the same as that used in extraction of a cataract. It is a true pocket and not merely a wide conjunctival flap as suggested by Holth and Elliot. The angles are not open near the cornea. This provides a large area of thick conjunctiva over the scleral opening, and the incision in the sclera is made in what is practically a sterile field, the possibility of infection thus being avoided. The danger of blocking the

⁴ Hall, R. J. Hydrochlorate of Cocaine. New York M. J. 40: 643 (Dec. 6) 1884.

scleral wound is circumvented by the iridodialysis Henderson⁵ examined microscopically thirty-three eyes after iridectomy. In each eye a tongue of iris remained attached at the ciliary body, the average width being 1.06 mm. In 1873, Bowman recommended tearing instead of cutting the iris in performing a broad iridectomy. Tearing permits a peripheral coloboma well back of the incision. The anatomic arrangement of the tissue at the base of the iris is such

Fig 5—Visual fields taken before and after operation giving the tension and vision

as to cause the rent to occur in the most favorable, i.e., most peripheral, portion of the ciliary zone of the iris. The forceps in the left hand hold the conjunctiva and fix the eye, while the root of the iris is torn with the iris forceps in the right hand. It is easier to tear the iris than it is to pull it out and do an iridectomy.

Possible injury to the lens has been suggested as an objection to this operation. No cataract has resulted in this series and seems a remote complication, as the iris is grasped on the anterior surface and thus protects the lens from any injury from the forceps. In some cases there has been moderate hemorrhage, but not more than follows iridectomy. The hyphema is entirely

Fig 6—Visual fields taken before and after operation showing the tension and vision

absorbed and causes no complications. The hemorrhage is an advantage rather than a disadvantage, as it acts as local autohemotherapy and tends to prevent infection.

Henderson⁵ stated that Fuchs has called attention to the fact that aseptic wounds of the iris are not followed by the formation of scar tissue. Injury of the iris, in the absence of hemorrhage and infection, shows little or no tendency to scar formation on healing. This is especially true if iridodialysis is performed,

for the iris is completely separated and there are no tags left at the base, as occurs after iridectomy.

SUMMARY

I now have records of twenty-eight eyes on which sclerecto-iridodialysis has been performed. The patients are all private patients, and have been under careful observation for from one to twenty-nine months.

Eight of the cases were in men, and twenty in women. The ages were as follows: from 40 to 50, four cases; from 50 to 60, six; from 60 to 70, twelve; and from 70 to 80, six.

There were five cases of acute inflammatory glaucoma and twenty-three of the chronic type. Among the latter, there were seven blind eyes with absolute glaucoma.

Tension—Following the operation, the pressure was reduced to normal limits in each eye, and has remained

so during the months of observation. Each patient has been comfortable and free from symptoms.

Fields—Four of the eyes showed slight contraction of the visual field after operation. In the remaining seventeen eyes, there was a definite increase in the size of the field.

Vision—Seven of the eyes were blind, owing to absolute glaucoma. The vision in three eyes was slightly reduced after operation, and in the other seventeen the vision was the same or better.

CONCLUSIONS

The cause of primary glaucoma is not known. The relief of the pressure symptoms by a decompression operation (sclerectomy) and the production of a filtrating cicatrix is based on sound surgical principles.

The pocket-flap of the conjunctiva gives a sterile field for the operation, lessens the danger of immediate and late infection and covers the opening in the sclera with firm protective tissue.

Iridodialysis removes the block of the angle of the anterior chamber better than iridectomy. No iris

remains at the base to cause recurrence (fig 2) There is no dazzle or glare after the operation, for the pupil is small, round and central (fig 3), and as the sphincter is not injured, miotics may be used after the operation

ABSTRACT OF DISCUSSION

DR. WAITER B. LANCASTER, Boston This operation may be classified as a modified Lagrange operation In my opinion, iridodialysis is an improvement over iridectomy as performed in the original Lagrange operation, with the following reservation What happens when the iris is atrophic? Does the tear or dialysis always occur at the very base of the iris? Some operators, myself included, have tried to secure good clearance of the angle by using a spatula to separate the synechia before doing the iridectomy or iridodialysis I did not succeed in devising a satisfactory technic, nor has any one developed a method of doing this which has received wide adoption Thiel advises a preliminary cyclodialysis

My feeling has been that an operation on the iris which permanently liberates the angle for 5 mm or more would relieve probably 60 per cent of cases of glaucoma If unsuccessful, a filtration operation could be performed

Dr Spratt makes comparison with iridencleisis The important basal fact concerning iridencleisis is that the presence of iris in the scleral incision greatly favors filtration However,

fistula ends in part under the split and very thin layer of cornea, which more easily makes a thin-walled, bulging bleb

I see no need or advantage in Dr Greenwood's technic of inserting the conjunctival sutures until the end of the operation They are in the way I see no advantage and some disadvantage in inserting the Graefe knife down and in, and then changing its direction to horizontal and making a counter-puncture It is easier to start with the blade horizontal for both puncture and counter-puncture The size of the interior

Fig 8—Visual fields taken before and after operation, giving the tension and vision

opening is the important thing The size of the exterior opening is unimportant

DR. VIRGIL J. SCHWARTZ, Minneapolis The fact that so many operative procedures have been proposed for the relief of glaucoma, not only varying in manner of execution but diametrically opposed in basic principle, is sufficient evidence that not one of them has thus far been found to be uniformly satisfactory Moreover, it is possible that until the fundamental cause of glaucoma in its various forms is discovered, there will be no unanimity on this subject Particularly is this true of so called chronic simple glaucoma I have had the opportunity of examining several of Dr Spratt's patients operated on by the method which he has just outlined, and I have been impressed by the excellence of the results There are several reasons why this should be so For one thing, he employs two of the more generally accepted operations together, the Lagrange sclerectomy and iridodialysis It might be argued that if either of these was entirely successful it

Fig 5—Visual fields taken before and after operation giving tension and vision

should not be necessary to do both The fact remains, however, that the reduction of tension produced by iridodialysis may not always be permanent so that removal of a piece of sclera is advisable

Dr Spratt fortifies his result by using the pocket-flap, which he has been employing in operations for cataract for several years Moreover, by tearing the iris instead of cutting it, he is fairly certain not to leave a margin of iris tissue at the base, as so often happens with iridectomy I have asked Dr Spratt whether there is not some danger of injuring the anterior cap-

Fig 7—Visual fields taken before and after operation, showing the tension and vision

it makes a great deal of difference how the iris is placed in the scleral incision The pigment epithelium is the important element It must not be folded on itself nor lacerated

Of the operations described by Dr Spratt, we have to make our choice among the following The Lagrange operation, or excision of the lip of the sclera, a modified Lagrange operation, iridencleisis, iridencleisis with excision of the lip—the Lagrange operation plus iridencleisis, iridencleisis with various ways of cutting the iris to prevent it from retracting into the eye The Elliot operation and the original Holth punch operation may be regarded as modified Lagrange operations

It is clear that no one of these has such a great advantage over the others as to make it the choice of the majority

The Elliot operation is easier to perform than most of the others There is much more likely to be a thin bleb, however I do not recall seeing any explanation for this, so I offer the following In Dr Spratt's technic the conjunctiva is dissected as for the Elliot operation A horizontal incision is made in the conjunctiva, the ends of which are carefully kept away from the limbus, all of the tissue down to the sclera is removed in a thick flap, the cornea is split, and a piece of sclera is excised—in these respects, there is no difference Why should there be a thinner bleb after the Elliot operation? It is because during this operation the hole in the eyeball is perpendicular to the surface and includes some of the cornea as well as sclera During the Lagrange and Spratt operations the hole is oblique, not perpendicular, and so does not include the corner Thus the split made in the cornea is permitted to close, and the fistula ends farther up under the conjunctiva This forms a good thick bleb much oftener than when the

sule of the lens while tearing the iris away from its attachment, but he assures me that the layer of iris tissue between the forceps and the lens provides a protective cushion which prevents danger to the lens

For those of us who are accustomed to firm fixation of the eye during incision, it would probably be somewhat difficult to rely on the suture through the superior rectus muscle, though the latter would be amply firm. Yet these difficulties can doubtless be surmounted. Many of Dr Spratt's patients with intra-ocular conditions are allowed to sit up within a startlingly short time after operation, often immediately afterward, and to leave the hospital within a few days. This is, of course, because of the firm support of the well sutured conjunctival flap. Dr Spratt's combined operation holds a great deal of promise.

DR CHARLES N SPRATT, Minneapolis. In all of the patients operated on, separation of the iris from the ciliary attachment occurred even when atrophy of the iris was present.

The presence of the thin layer of conjunctiva which follows the trephining operation and which is absent after the Lagrange method can be explained by the fact that the pressure exerted on the tissue from a round opening tends to cause thinning at the center. In contrast, the wound in a Lagrange operation is 3 mm or more long, and the stretching takes place over its entire width.

For many years I did the iris inclusion operation, but abandoned it for two reasons: the bulging areas of conjunctiva and one case of panophthalmitis due to late infection.

Fig 10—Visual fields taken before and after operation showing the tension and vision

Excellent fixation of the eye is secured by holding the conjunctival flap with blunt forceps. Sharp mouse tooth forceps may cause tearing of the flap. The eye is easily rotated downward by gentle traction. The pull on the conjunctiva is distributed over a wide area of attachment. In addition, I usually place a suture in the superior rectus muscle. It has been suggested that sutures be placed in both lateral rectus muscles.

The insertion of the suture in the conjunctiva previous to scleral incision is of great importance, as it is easily and safely done at the time, and should loss of vitreous threaten immediate closure is possible. It is both dangerous and difficult to place a suture when a prolapse threatens.

No injury to the lens has occurred, as the iris is grasped by the forceps preventing contact of the latter and the lens.

The Most Important Cause of Disease—Fatigue is perhaps the most frequent and most important single cause of disease and under its influence one local manifestation after another often functional but often also organic in nature may develop or there may be a simultaneous appearance of several diseases. Each of these may perhaps be skilfully treated as purely local conditions but when the source of trouble is uncorrected each successful local treatment may be followed by new outbreaks. Those who were fortunate enough to have known Weir Mitchell or are familiar with his contributions will not need to be told that his recognition of fatigue as a cause of disease and his practical system for its correction were his great contribution to medicine—Stengel Alfred. *The Internist* His Own Psychiatrist. *Ann Int Med* 7:281 (Sept) 1933.

EFFECT OF VACCINATION WITH BCG ON CHILDREN FROM TUBERCULOUS FAMILIES

WILLIAM H PARK, MD
CAMILLE KERESZTURI MD
AND
LUCY MISHULOW, AB
NEW YORK

In the April 8, 1933, issue of THE JOURNAL there appeared an interesting article by Chester A Stewart of Minneapolis.¹ The author holds that accidental primary infection with the human tubercle bacillus, even when it does not produce manifest disease, is disadvantageous from the point of view of later endogenous or exogenous tuberculous infection. The allergic stage, according to the article, does not confer immunity but rather increases susceptibility. This point of view, if true, has an important bearing not only on our present attitude toward arrested tuberculous infections but also on the desirability of producing an artificial allergy to tuberculin by means of attenuated vaccines like the BCG vaccine of Calmette. Our aim by this form of attempted immunization is to give to the child who is believed to be not yet infected, or, at least, not seriously so, as shown by a negative reaction to tuberculin, its first tuberculous infection in a safe, well calculated way.

This vaccination depends on a belief exactly the reverse of the thesis of Stewart. We assume that hypersensitiveness to tuberculin and relative immunity to tuberculous infection usually develop together, and also that resistance to reinfection may outlast hypersensitiveness to tuberculin.

We thoroughly agree with Dr Stewart that consumption never develops in persons with a negative reaction to tuberculin without a previous first infection. We also believe that the first infection may be so massive or the child so susceptible that it does not cease in the primary stage but progresses to the secondary or tertiary acute or chronic forms. We are not even surprised that his eighty-four children happened to belong to this group, because sixty-five of the eighty, a total of 81 per cent, had intrafamilial exposure, which naturally renders them a highly endangered and highly selected group. Therefore, we suspect that in his selected eighty-four consumptive children the exposure was usually the determining factor. Our suspicion is borne out by the fact that forty-four of the eighty children who gave positive reactions had the adult type of chronic tuberculosis at the first examination, which means that they are not at all comparable

From the Department of Health.
Read before the Section on Pediatrics at the Eighty Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.
Because of lack of space the article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the authors' reprints.

This study was begun on Dec 15, 1926 and was made possible by the cooperation of the hospitals and clinics of New York City. The clinic facilities for our follow-up work were made possible by the children's services of Bellevue, Fifth Avenue, Harlem, Long Island College, Greenpoint, Babies and Sea View Hospitals. The financial support of our study was made by the Metropolitan Life Insurance Co. and the Milbank Memorial Fund. Our staff consists of Peter Vogel, MD, and Milton I. Levine, MD, assistant pediatricians; M. Sackelt, RN, nurse-in-charge; R. Stebbins, RN, and G. Richardson, RN, assistant nurses; Mr. A. Teach, social worker; and R. Weber and M. O'Connor, clerks. Dr. Rustin McIntosh, Dr. Louis I. Dublin, Dr. Bela Schick, and Dr. Emil Bogen helped us by their creative criticisms. Dr. John Caffey read our roentgenograms.

¹ Stewart Chester A. Does a Primary Tuberculous Infection Afford Adequate Protection Against Consumption? *J A M A* 100:1077 (April 8) 1933.

with those with negative reactions, not only as far as exposure was concerned, but also because they had manifest clinical tuberculosis when selected for study of the effect of primary tuberculosis on them. If one wishes to compare fairly children who react negatively to tuberculin with those who react positively from the point of view of immunity, the two groups must be the same in every other important respect except the reaction to tuberculin. If the age, length of observation and degree and length of exposure of the two groups are the same, they can be evaluated fairly as to the beneficial or the deleterious effect of the primary infection in the face of further exposure.

We observed that among the 224 parenterally vaccinated children there were no deaths from tuberculosis, and that 85 per cent of these children showed at some time a positive reaction to tuberculin, whereas among the 272 orally vaccinated children, among whom the frequency of positive reactors was much more rare, we observed 3 deaths from tuberculosis. However, some of the difference in the death rate can be attributed to the fact that the parenterally vaccinated children were not vaccinated at birth, whereas the BCG vaccine, when fed, had to be given within the first ten days after birth. Therefore, the latter group of children had more chance to become fatally infected. In order to eliminate this difference between the two groups, we now try to administer the BCG vaccine by injection to as many new-born infants coming from tuberculous families as we can find in New York City. If, after equilibrating the age of the two groups of children, the difference in the mortality still persists, we can consider this fact as contradictory evidence to the belief of Stewart.

We have another group of children, study of whom might interest Dr Stewart. Parallel with the children parenterally vaccinated with BCG, we studied a number of unvaccinated controls who had an initially negative reaction to tuberculin and another group who came to us with positive initial Mantoux reactions, all of the groups came from tuberculous families. Most of these children were less than 1 year of age when first tested, however, some of them had passed their third year at the time we had the opportunity to

TABLE 1—Cases with Negative Initial Roentgenograms of the Chest

Positive Initial Mantoux Test			Negative Initial Mantoux Test		
Total Number of Cases	Deaths from Tuberculosis	Deaths from Non tuberculous Conditions	Total Number of Cases	Deaths from Tuberculosis	Deaths from Non tuberculous Conditions
31	1 3.2%	2 6.4%	79	3 3.8%	4 5.0%

perform a Mantoux test on them. The routine dose was 0.2 mg of old tuberculin, given intradermally. The length of the follow-up study of these children varied from one-half to five years. In connection with Dr Stewart's thesis, we studied only those children whose x-ray pictures of the chest showed nothing abnormal at the time or within two months of the time of the first tuberculin test. There is no point in including children who showed roentgenologic evidence of tuberculosis at the first examination or on whom no roentgen examination of the chest was made when they were seen, because we agree with Dr Stewart and others that a too massive initial infection which

produces manifest signs of the disease is a great risk and probably does not confer any appreciable immunity.

We omitted from tables 1 and 2 those children who died of tuberculosis within three months after the initial tuberculin test. We did this in order to be sure that the first tuberculin test was significant and was not done during the negative allergic stage.

As far as the exposure was concerned, we considered it for the positive Mantoux cases from the first tuberculin test onward and for the negative Mantoux test

TABLE 2—Exposure to Tuberculosis

Exposure	Positive Initial Mantoux Test		Negative Initial Mantoux Test	
	Number	Percentage	Number	Percentage
Positive sputum	15	48	41	52
Negative sputum	2	6	24	30
No known exposure	14	40	14	18

* If exposure is considered from the time of the first tuberculin test onward the percentages change to 50 for children exposed to positive sputum 2, for those exposed to negative sputum and 34 for children with no known exposure.

group, from three months prior to the first tuberculin test onward.

As far as the death rate from tuberculosis is concerned, the two groups run almost parallel. This fact suggests that at least in the period immediately following accidental tuberculous primary infection without other evidence of tuberculosis than a positive Mantoux reaction to 0.2 mg of old tuberculin children do not do as badly as Dr Stewart would think. As all the children with positive reactions to tuberculin in our group were very young, they must have had fresh infections, yet they showed about the same death rate from tuberculosis as did those with negative reactions. Therefore, we think that as the tuberculous lesions heal the children will not do worse even later on, whereas those with negative reactions still have to go through their first fresh infection with its attendant risk of early dissemination sometime later. When Dr Stewart claims that primary tuberculous infection is always a benign form of tuberculosis, he seems to overlook the group of children who died of acute forms of tuberculosis, such as tuberculous meningitis and miliary tuberculosis, shortly after the first infection.

We have discussed Dr Stewart's paper at length because we felt that it has great significance for the underlying principles of our immunization of children of tuberculous families with BCG. We shall now discuss our results with vaccination from the points of view of mortality, reactions to tuberculin tests and roentgen findings in the chest.

DIFFERENCE IN MORTALITY FOR CHILDREN VACCINATED WITH BCG AND CONTROL CHILDREN

In order to show the difference between children of tuberculous families after vaccination with BCG and children of tuberculous families without vaccination with BCG, we present two groups for consideration. The first group consists of all the children used as controls who entered our study at birth and all the children whom we vaccinated orally with BCG (table 3). Among the dead babies, only those are included who would be at least 1 year old by June 1, 1933, if alive. Among the living babies, also, credit is given only for completed years.

As is seen from table 3, the children vaccinated with BCG show a lower death rate from tuberculosis than do similar controls. This is true in spite of the fact that we included among the children orally vaccinated with BCG two whose death was caused by a condition of suggestive tuberculous origin, though it was not definitely proved to be so. In all of the cases the exposure to tuberculosis was determined from birth onward. During the first year of life, about one fourth of the children vaccinated with BCG and one third of the controls were exposed to tuberculosis. During later years, however, the exposure was fairly parallel in the

As we had no other facilities to do this, we left the children in the hospitals during the new-born period for one or two months, but we soon found that quite a number of them contracted intercurrent diseases and died shortly after birth of alimentary intoxication, bronchiopneumonia and other conditions. Therefore, we abandoned this method, and we do not hospitalize new-born infants for the sake of separation any more. If we disregard the eleven deaths from nontuberculous conditions among the orally vaccinated children and the two deaths from nontuberculous conditions among the controls, which occurred within 3 months of age in

TABLE 3—Mortality Among Children Orally Vaccinated with BCG and Children Used as Controls, Known Since Birth

Age Months	Type of Case	Total Number		Exposed to Positive Sputum		Exposed to Negative Sputum		No Known Exposure	
		Total	Deaths from Tuberculosis	Total	Deaths from Tuberculosis	Total	Deaths from Tuberculosis	Total	Deaths from Tuberculosis
0-12	BCG	239	2 0.8%	61	2 3.3%	91		87	
	Control	189	6 3.2%	54	5 9.2%	90	1 1.1%	45	
12-24	BCG	192		53		75		64

TABLE 4—Mortality Among Children Parenterally Vaccinated with BCG as Compared with That for Controls with Negative and Those with Positive Initial Mantoux Reactions

Roentgen Findings in Chest	Children Parenterally Vaccinated with BCG			Controls with Positive Initial Mantoux Reactions			Controls with Negative Initial Mantoux Reactions		
	Total Number of Cases	Deaths from Tuberculosis	Deaths from Non-tuberculous Conditions	Total Number of Cases	Deaths from Tuberculosis	Deaths from Non-tuberculous Conditions	Total Number of Cases	Deaths from Tuberculosis	Deaths from Non-tuberculous Conditions
No abnormality	91		2 2.2%	31	1 3.2%	2 6.4%	79	3 3.8%	4 5.0%
Glandular pathologic change	11			6			5		
Parenchymal pathologic change	8			23	2 9.0%		2		1
No roentgenogram	49		3 6.6%	95	2 2.0%		183	1 0.5%	6 3.2%
Total number of cases	150		5 3.3%	155	5 3.2%	2 1.3%	269	4 1.4%	11 4.0%
Exposure to positive sputum	83 55.3%			60 38.0%			107 39.8%		
Exposure to negative sputum	25 17.0%			19 12.0%			72 26.8%		

two groups. All of the deaths from tuberculosis occurred in the exposed groups and within the first three years. It should be remembered that each consecutive year the numbers became less. The mortality from nontuberculous conditions was not lower in the vaccinated group than in the control group, therefore we have no evidence to assume "paraspecific immunity" due to vaccination with BCG as described by Calmette. As a matter of fact there was a greater number of deaths from nontuberculous conditions during the first year among the children orally vaccinated with BCG than among the controls. However we can explain the difference as follows. Calmette advised us to keep the vaccinated children separated from their tuberculous foci for one month after immunization.

the group of hospitalized children, as being due to intercurrent infections contracted in the hospital, then the death rate for nontuberculous conditions in the first year is 4.2 per cent for the orally vaccinated children and also the same for the controls. The similarity of these two figures indicates that our explanation as to the dissimilarity of the death rate for nontuberculous conditions among vaccinated and nonvaccinated children was due to the unequal hospitalization of the two groups during the new-born period.

The other group in which we studied the effect of vaccination with BCG was composed of children whom we did not know at birth, but who had a negative reaction to tuberculin in amounts up to 10 mg when first examined and who received the Calmette

vaccine intradermally or subcutaneously after the initial examination. These children also came from tuberculous families. The mortality among these children was contrasted with that among similar children with negative Mantoux reactions who were not given the vaccine. The second control group to the parenterally vaccinated children consists of infants who, when first examined, were naturally infected, as demonstrated by a positive tuberculin test with or without roentgen evidence of infection (table 4).

As is seen from table 4, the children parenterally vaccinated with BCG did not show any mortality from tuberculosis, whereas the controls with negative Mantoux reactions had a death rate of 14 per cent, against 32 per cent among the children with positive initial Mantoux reactions. If we disregard the children who had initial parenchymal lesions and those for whom no initial roentgenograms of the chest were

we used this group to study the frequency of positive tuberculin tests according to exposure and age. Two hundred and five children vaccinated with BCG and 148 control children were used for this study. The remainder either had not finished their first year or were not tested for allergy. For this study we considered only the Mantoux tests performed with 0.2 mg of old tuberculin, and omitted those negative tests which were done with less than this standard dose and those which were positive with a higher dose. Only children who had finished their first, second, third or fourth year of life were considered.

We have assumed that throughout the period between two negative tests another injection of tuberculin would also have given negative results. A similar assumption has been made with respect to consecutive positive tests. If no test was made at the end of a given year but tests were made before and after this time, we assumed that the reaction at the end of the particular year would, if the test had been made, have been the same as the reactions to tests made before and afterward.

However, this method cannot be used if two dissimilar reactions are obtained. Therefore, we have made special groups of those cases in which the tuberculin test changed from negative to positive and from positive to negative. Our rule for this study, as far as exposure is concerned, has been to put the child in the "no known tuberculous exposure" group for the period before the exposure took place, and in the exposed group from the time of exposure on. In this way our total number of cases fell in one of three categories: (1) not exposed, (2) exposed to a tuberculous member of the household whose sputum was apparently negative and (3) exposed to a member of the family whose sputum was positive. We have also separated the children vaccinated with BCG in each group from the similarly exposed controls (fig. 1).

Because of the small number of cases in each subgroup, the percentages have little statistical significance but are nevertheless of value. As is seen from figure 1, the frequency of positive tests increases with age and with exposure. In each group the vaccinated children gave a higher percentage of positive and changing reactions than did similar controls. However, it was surprising to us to see that even among the controls there were a small number of patients who reacted positively to the same doses of old tuberculin to which they later reacted negatively. Some of these changes undoubtedly were real, some less than 2 cm in diameter, however, might have been pseudoreactions. As we did no control tests, we are unable to distinguish definitely the two types of reactions. Throughout the study we considered a test positive if the erythema or infiltration at the site of injection measured 10 mm or more in diameter when 0.2 mg of old tuberculin was used intradermally. It was interesting to us to learn from this study that only in 20 per cent of the controls did the test become positive within the first year of life, even though all of them were definitely exposed to a member of their family with open tuberculosis. This figure increased by the end of the fourth year to 50 per cent. In each group and at each age the children vaccinated with BCG showed a greater frequency of positive reactions than the controls. However, the difference only varied between 20 and 40 per cent. Therefore, if the development of a positive reaction to

Fig. 1.—Results of Mantoux tests performed on children orally vaccinated with BCG and on control children. All of the children had been known from birth. The dose was 0.2 mg of old tuberculin. The total number of controls was 148, the total number of children vaccinated 205. The solid black areas represent positive Mantoux reactions, the crossed areas a change from a negative to a positive Mantoux reaction, the dotted areas a change from a positive to a negative reaction and white areas negative Mantoux reactions.

made, the mortality from tuberculosis among the children with positive initial Mantoux reactions and that among those with negative reactions would be the same. Roughly, the exposure was the same in the three groups and was considered to affect the parenterally vaccinated children from three months prior to the inoculation, and the controls who had negative initial Mantoux reactions, from three months prior to the first test. On the other hand, the exposure in the group of children who had a positive initial tuberculin test was considered only from the date of the initial positive Mantoux test.

As is seen from tables 3 and 4, the mortality from tuberculosis among children vaccinated with BCG is definitely lower than that for corresponding controls.

RESULTS OF MANTOUX TESTS ON ORALLY VACCINATED AND CONTROL CHILDREN

As only the children known from birth were an unselected group as far as tuberculin tests were concerned,

tuberculin is the necessary indication of a successful vaccination with BCG, only from 20 to 40 per cent of the orally vaccinated children can be considered as effectively vaccinated

Table 5 shows that glandular and parenchymatous pathologic changes occurred more frequently among the controls than among corresponding vaccinated groups. Sometimes before death the roentgenograms of 81 per cent of the infants who died of tuberculosis showed pathologic changes in the parenchyma of the lungs against 8 per cent of those who did not die of tuberculosis. On first thought this roentgen study would seem to indicate that of the children who did not die of tuberculosis, the group vaccinated with BCG showed less morbidity as demonstrated by the x-rays than did corresponding controls. However, we do not think that the difference is significant, because the correlation between pathologic changes in the chest as demonstrated by roentgenograms, and tuberculosis is quite remote. We base this statement on the fact that in twelve, or 16 per cent, of the seventy-three cases in which parenchymal pathologic changes were found, the tuberculin tests were negative at or around the time the roentgenograms were taken. No reason could be found to explain the pulmonary lesions which were demonstrated by roentgenograms. In twenty-eight, or 48 per cent of the fifty-eight cases which showed enlarged hilar or paratracheal shadows, the tuberculin tests were negative at the same time. We are convinced that the reading of the roentgenograms of the chest was correct, however, we have no explanation for the positive roentgen findings. If we consider the tuberculin test a reliable means of diagnosis for tuberculosis, we must admit that the margin of error in the interpretation of roentgenograms of the chests of young children is so great that it is not safe to stress the slight difference between the pathologic changes found in the children vaccinated with BCG and in the controls.

VIRULENCE OF BCG

We shall now consider the virulence of BCG when cultured under special conditions favorable to an increase in virulence. The controversy concerning the possibility of the greatly attenuated BCG culture regaining its original virulence under certain special conditions has been followed by us with great interest and has been the subject of constant investigation. As is well known, Petroff and Sasano and Medlar in this country, Watson in Canada and Dreyer and Vollum in England have stated that it is possible to increase the virulence of the BCG by special methods of cultivation to such an extent that it will produce generalized progressive tuberculosis in guinea-pigs. Because of these results it was claimed that the inoculation of BCG into infants might be dangerous, as the culture might conceivably regain its virulence in the human body as it had in the special mediums. With this in view, we began an investigation which consisted of three main experiments.

1 An attempt was made to detect any appreciable increase in the virulence of BCG under the special methods of cultivation and animal inoculation utilized by those who believed they had seen an increase in virulence.

2 A study was made to determine whether any change in the virulence of BCG developed during residence in the human body for different periods.

3 Observations were made on the development of an increase or a decrease in resistance to tuberculous infection developed in animals after vaccination with BCG.

During the course of these studies it was found that the colonies of BCG on Bordet-Gengou's and on Loewenstein's medium are so characteristic that they can be readily differentiated from those of virulent human and bovine types of tubercle bacilli. Repeated tests showed that these characteristics were constant. Therefore, a study of the colony morphology of BCG was made in all of our subsequent tests in order to follow any changes in the characteristics of the colonies which might correspond to the changes in the virulence of this culture.

A series of experiments was carried out to test the methods recommended by Sasano and Medlar, Dreyer and Vollum and Petroff in an effort to increase the virulence of the bacilli. The BCG was carried through eleven generations on Sasano and Medlar's medium and through five generations on Dreyer and Vollum's

Fig. 2.—Typical colonies of tubercle bacilli after six weeks of incubation at 37°C. A, C, and E show the growth on Bordet-Gengou's medium. B and D, that on Loewenstein's medium.

medium. The culture was plated on Bordet-Gengou's and on Loewenstein's mediums, and tests for virulence were made at each transplant to the succeeding generation. Throughout the entire experiment, there was no change from the typical colony morphology.

A large number of rabbits and guinea-pigs were used during this experiment to test the virulence of the culture at each transplant. Some of them died of other infections. Of the sixty-nine rabbits and sixty-seven guinea-pigs that survived, all were negative except one rabbit and one guinea-pig. These two showed a sub-acute fatal generalized tuberculosis. Both of these animals, as well as five other rabbits and five guinea-pigs, were inoculated with the growth from the same bottle. All of the others were free from tuberculosis, although some of them survived as long as from 447 to 479 days. The rabbit in which tuberculosis developed died 340 days after inoculation, and the culture obtained from it was of the bovine type. The guinea-pig died 128 days after inoculation, and the culture obtained was of the human type. The fact that two different types of

tubercle bacilli were obtained from the growth of the same culture would, to a bacteriologist, be sufficient evidence that in at least one and probably in both of the animals it was a cross-infection from other sources

Owing to lack of space, these animals were handled by the same keeper and were kept in the same room with other animals that were inoculated with virulent human and bovine types of tubercle bacilli, and there is no doubt in our minds that cross-infection had taken place. During the past nine months the animals inoculated with BCG have been completely separated from the other animals, and no further progressive infections have developed. Opie has reported similar cross-infections, which have also occurred at the Saranac Laboratory and elsewhere.

The attempt to increase the virulence of BCG by Petroff's method of fishing out colonies from gentian violet egg medium and by rapid passage through guinea-pigs by intratesticular inoculation was also unsuccessful. Among the many guinea-pigs used in these tests, only one developed a mild generalized tuberculosis. But

PATHOLOGIC SPECIMENS FROM AUTOPSIES ON CHILDREN

We obtained pathologic specimens from seven children at autopsy. Five of the children were vaccinated orally during the first week of life, two were vaccinated intradermally and three were unvaccinated children from tuberculous families and served as controls. Table 7, which appears in the reprints, gives the details of these examinations.

The results show that no acid-fast bacilli were found in the organs of three of the infants who died of non-tuberculous infections ten days, thirty-four days and one year, respectively, after vaccination. The colony morphology of the culture that was obtained from the mesenteric glands of the infant who died thirty days after oral vaccination of alimentary intoxication was typically like that of the BCG vaccine strain and was nonvirulent. Human type tubercle bacilli were obtained from two of the infants who died of tuberculosis seven and one-half months and two years and eight months, respectively, after vaccination. Both of these children

* D indicates that the animal died of other infections. K that it was killed.

since the animals were not segregated at the time, it is more than likely that this case was another one of cross-infection. Most laboratories are now separating the animals infected with BCG from all others. The cultures of BCG are also segregated from all other cultures. Since these precautions have been taken there have been few, if any, reports of increased virulence in BCG cultures.

The question of the possible increase in virulence of BCG after its residence in the human body was investigated. Specimens of pus were obtained from the cold abscesses occasionally developing in children at the point of subcutaneous inoculation with the BCG vaccine. These specimens were cultured on Bordet-Gengou's and Loewenstein's medium, and when growth was obtained it was tested for virulence in rabbits and in guinea-pigs. In some of the cases we obtained more than one specimen of pus. We were able to obtain and study in this manner cultures from six children from three and one-half to six months after vaccination.

All of the cultures were typically like BCG in colony morphology on Bordet-Gengou's and Loewenstein's mediums and showed no increased virulence for rabbits and guinea-pigs.

had whooping cough which in all probability lowered their resistance to infection from a human source. The result of the examination of the last intradermally vaccinated infant who died of pneumonia seven and one-half months after vaccination is incomplete as to animal inoculation, but is negative on smear and culture, and the guinea-pigs are negative to tuberculin after two and one-half months of incubation.

SUMMARY

1 From the results of these investigations it appears that BCG is so attenuated that even under the most favorable conditions of artificial cultivation it is difficult to increase its virulence to any degree. During the past five years, the virulence of the BCG vaccine was tested on 165 rabbits and 194 guinea-pigs, but no evidence was found of any increase in virulence. Twenty cultures of acid-fast bacilli that were recovered from the cold abscesses of seventeen children after from one to six months' stay in the body showed no increase of virulence, but remained like the BCG in colony morphology and were nonvirulent for rabbits and guinea-pigs.

One culture was recovered from the mesentery of an orally vaccinated child six weeks after vaccination.

This culture showed no increased virulence and culturally was typically like BCG

The pathologic material that was obtained from children who were vaccinated with BCG and died of other infections showed no evidence that BCG tended to increase in virulence during its residence in the human body

2 On the basis of our limited experience and on the basis of publications of others, we do not think that slight primary tuberculous infection acquired by natural infection or produced by vaccination diminishes resistance against future superinfections by tuberculosis

3 Children of tuberculous families vaccinated orally with BCG show lower mortality from tuberculosis than corresponding controls

4 None of the parenterally vaccinated children died of tuberculosis, whereas the children who were not vaccinated and were similarly exposed showed about 3 per cent mortality from tuberculosis. There was no appreciable difference in the mortality of the controls who had negative roentgen findings in the chest when they were first seen whether they had negative or positive initial tuberculin tests

5 Tuberculin tests performed on 148 nonvaccinated children followed up since birth and on 205 children orally vaccinated with BCG before their tenth day showed, during the first two years of life, from 20 to 40 per cent more positive Mantoux tests among the latter cases. The allergy produced by BCG apparently does not usually last for more than two or three years

6 Comparatively few of the control children developed positive reactions to tuberculin, even when they were more or less exposed to open tuberculosis, i.e., 20 per cent in the first year and 50 per cent up to the fourth year

7 If repeated tuberculin tests are performed through the years, a small percentage of the slightly or moderately positive reactions become negative

ABSTRACT OF DISCUSSION

DR HORTON R. CASPARIS, Nashville, Tenn. Since the chief specific immunity comes from infection, this particular means was made use of to give the relative degree of immunity that comes from infection. I am glad that the authors mention experimental evidence to the effect that there is a relative degree of immunity that goes with infection, and that they more or less combat the views expressed by Stewart who I think has several loopholes in his argument that children who have been previously infected are more susceptible. In the first place, it is quite impossible to prove that the children in whom pulmonary tuberculosis has developed have not had overwhelming infections. He has no evidence that those children did not have in their past repeated small infections, without symptoms until they were subjected to overwhelming infections. From the practical standpoint one is justified in giving BCG when one is tolerably certain that individuals will be exposed to unknown amounts of virulent human organisms. Physicians in Nashville have had occasion to observe many of about 5000 children who have received BCG but the treatment was given without the elaborate control measures that the authors have described. Of course it will never be definitely known whether or not anything is being obtained from that without the control measures.

DR KARI F. KASSOWITZ, Milwaukee. The general adoption of BCG vaccination seems to rest on two essential questions. Can the method be considered not only 100 per cent safe but rather 110 per cent fool proof? Should it replace complete with or rather supplement the methods of social hygiene namely detection of sources of infection and isolation?

On the basis of our limited experience and on the basis of publications of others, we do not think that slight primary tuberculous infection acquired by natural infection or produced by vaccination diminishes resistance against future superinfections by tuberculosis. Children of tuberculous families vaccinated orally with BCG show lower mortality from tuberculosis than corresponding controls. None of the parenterally vaccinated children died of tuberculosis, whereas the children who were not vaccinated and were similarly exposed showed about 3 per cent mortality from tuberculosis. There was no appreciable difference in the mortality of the controls who had negative roentgen findings in the chest when they were first seen whether they had negative or positive initial tuberculin tests. Tuberculin tests performed on 148 nonvaccinated children followed up since birth and on 205 children orally vaccinated with BCG before their tenth day showed, during the first two years of life, from 20 to 40 per cent more positive Mantoux tests among the latter cases. The allergy produced by BCG apparently does not usually last for more than two or three years. Comparatively few of the control children developed positive reactions to tuberculin, even when they were more or less exposed to open tuberculosis, i.e., 20 per cent in the first year and 50 per cent up to the fourth year. If repeated tuberculin tests are performed through the years, a small percentage of the slightly or moderately positive reactions become negative.

remains no doubt that the cultures as used by Dr Park and his associates would prove just as harmless in the amount of 10 mg orally and from 0.01 to 0.05 mg parenterally if furnished by him to other physicians of other communities. The question of dosage, the physical condition of the child and the evaluation of the sociomedical factors of exposure, nutrition, and so on require a more judicious handling than other prophylactic procedures. Yet the fact of avirulence of the BCG culture in children, as confirmed by the authors, will eventually make the general use of this method inevitable. The second question is how to coordinate the method of preinfectious vaccination and postvaccinal exposure to infection with the principle of detection and removal of all sources of infection within the reach of a child, as it is being practiced by all public health agencies at the present time, more or less conscientiously and efficiently. I feel that the lesser incidence of tuberculosis in some parts of the country, especially in communities of the Middle West (from 4 to 30 per cent positive tuberculin reactors of the total population in Wisconsin towns) compared with the East, particularly New York and Philadelphia, may account for a greater optimism concerning the possibility of a detubercularized environment. However, exposure to tuberculosis will for some time be an actual danger, because it will not be possible to isolate the potential tuberculosis carriers in the form of sputum-negative, tuberculin-positive reactors. The most desirable object of the vaccination method is to anticipate the primary infection in children of these potential tuberculosis carriers. The artificial rise of resistance against casual superinfection has been borne out sufficiently by the figures of Dr Park and European authors, like Heimbeck. Yet, in case of a constant exposure to a frank, open tuberculosis, the possibility of an overwhelming superinfection after BCG vaccination has not yet been disproved.

DR HENRY J. GERSTENBERGER, Cleveland. I wish to ask the authors two questions. Do they consider their work extensive enough to warrant its trial in other communities? Is the difference between 1 per cent and 3 per cent big enough to warrant the immunization with BCG? I understand that the mortality rate in the controls was 3 per cent.

DR J. A. MYERS, Minneapolis. When a child is infected with tubercle bacilli to the point of producing allergy, foci of tuberculous disease are in his body. Such foci constitute a liability rather than an asset, since they contain cultures of tubercle bacilli which at any moment may be disseminated to other parts of the body. Moreover, allergy is a liability. The first infection type of disease always precedes both acute and chronic reinfection or destructive types. Therefore, the first infection type cannot be regarded as an asset. The records at L. J. Manhurst, including Stewart's recent report, have shown that the children with the old first infection type of disease have provided nearly all of our consumptives in the teen ages and early twenties. Heimbeck's tuberculin-negative nurses developed the first infection type of tuberculosis, just as most infants and children develop this type when first infected. A few of these girls have already died, as one would expect, from dissemination of bacilli from their primary foci (endogenous reinfection) or exposure to outside sources (exogenous reinfection). Among our students of nursing and medicine who have become infected for the first time through exposure to patients, I have not seen one develop rapidly destructive tuberculosis. Their lesions when demonstrable by tuberculin and roentgen examinations have been of the benign, first infection type. No symptoms appeared except in the occasional case of pleurisy with effusion or erythema nodosum. Two have fallen ill with the reinfection type of disease, many months after the first infection type was demonstrated. If allergy produced by BCG is as dangerous and persistent as that produced by virulent bacilli, one must reap a harvest of tuberculosis among the inoculated group during their teens and twenties just as such a harvest is being reaped among those of this age period who were accidentally infected when they were infants and children. One must not ignore the work of Feldman, Petroff and others who have produced destructive tuberculosis in animals by inoculating cultures prepared from BCG. The remote dangers may also be great. To tide over the age period from birth to three years, when acute reinfection forms of tuberculosis occur, the

methods of Grancher, Bernard, Hess and others have proved efficacious. They possess none of the possible dangers of BCG. I admire the scientific and investigative spirit of such workers as Drs. Park and Calmette, but I would feel less apprehensive about the future health of the children of the world if vaccinations with BCG would cease until observation and time tell of the remote outcome of more than 1,000,000 children in Europe, and a smaller number in America who have received this vaccination. The material is sufficiently large, but almost a quarter of a century must pass before definite conclusions are justified.

DR EMIL BOGEN, Olive View, Calif. During the past month I had the opportunity to examine carefully the work of the New York investigation, and I can testify to the great care and precautions taken against errors. They have elaborate data on the 1,000 children that have been followed during the past five years. In interpretation of the data, though, there are many pitfalls. It appears that the danger of BCG becoming virulent is practically nil. On the other hand, there is a possible danger of inoculating a child already infected with tuberculosis but not yet recognized as such with tuberculin or bacillus, as BCG contains tuberculin. There have been a few cases suggesting that in such cases BCG may do harm. Animal experiments have been cited to show that BCG gives protection, but the protection given has been practically uniform against subcutaneous infection. There has not yet been sufficient evidence that the protection would be exerted against a respiratory infection in animals. Calmette, as Dr. Park stated, believes in a specific immunity, that BCG gives children better health. The New York investigation indicates that, if anything, it has a deleterious effect on general health. I have found in practical clinical experience that the tuberculin test is a very valuable guide in the diagnosis of tuberculosis in infancy, just as in veterinary practice the tuberculin test is a very valuable guide for detecting the presence of tuberculosis in cattle. It may still be questioned whether it is worth while losing the diagnostic value of a tuberculin test by vaccinating the infants against the disease.

DR WILLIAM H. PARK, New York. It seems to me that in his discussion Dr. Myers forgets that among the children who developed an infection during the first few months of life a certain percentage die from acute disseminated tuberculosis. In New York City at present we know from our vital statistics that the number of deaths from this cause is at least 40 in infants under 1 year of age. I think Dr. Myers misunderstands the position of those who believe that an arrested infection is under certain conditions a protection. We believe that an arrested infection is a possible danger and therefore of no advantage to a child who is not to be exposed but that it is a protection against further infection, so that on the whole it is advantageous for a child who is to be repeatedly infected. Our hope is that the BCG gives the protection without any possibility of the vaccine itself causing actual tuberculosis. As "consumption" is always a tertiary stage there must of course be a primary focus before clinical pulmonary tuberculosis develops, but as probably 80 per cent of us in this audience have a positive Mantoux test, we certainly hope that only few of us will ever develop pulmonary tuberculosis. As to whether I think we have had sufficient experience to make it wise to advocate the general use of BCG I believe it is safe and I think the evidence suggests strongly that it gives some protection. I advocate it for infants and older children who have a negative Mantoux test and are to be exposed to infection, if the conditions insure the careful preparation and administration of the vaccine. Probably it is wise to use the vaccine at the present time only as Milwaukee is doing, in certain selected groups, so that its practical value may be decided later. Statistically, the New York City results are not conclusive because they deal with comparatively small numbers of both vaccinated and not vaccinated children. The members of the tuberculous families are instructed as to the precautions necessary to protect their children, whether they are BCG cases or controls. Partly because of this advice surprisingly few of the exposed unvaccinated children die and therefore the difference in the death rate is not as great as it would probably be if no advice were given. I want to acknowledge the great value we

obtained from Dr. Bogen's visit. We hope he will come back next winter. We needed a critical survey of our work by somebody of his type, who combined knowledge of tuberculosis with a knowledge of statistics and mathematics. We agree with him that the hospitalization of infants to prevent infection is usually unwise because it probably causes the death of more babies from nontuberculous infections than it saves from deaths from tuberculous infections. As far as I see, vaccination with BCG does not influence the death rate from other infections than tuberculosis. We think that in only giving the vaccine to exposed children who show no positive reaction to the Mantoux test, we avoid the risk of injuring any from the BCG vaccination. We certainly have never noted any harm from it. I entirely agree with all that Dr. Kassowitz said.

RESULTS OF SURGERY IN SPINA BIFIDA

ANATOLE KOLODNY, M.D.

SIoux CITY, IOWA

According to the literature the operative mortality in spina bifida is extremely high. In 1905, Moore¹ reported a mortality of 50 per cent, computed from a study of reports of treatment of some 378 cases. Twenty years later, Cutler² stated that this mortality was at least as high as 60 per cent, basing his conclusions on a study of sixty-five cases from the Children's Hospital in Boston. In 1929, the experience of the Mayo Clinic showed a mortality of about 50 per cent if operation is carried out at a young age.³ There is little wonder that with these figures at hand, the general practitioner and the obstetrician who are the first to come in contact with these cases, hesitate to recommend early surgical treatment, notwithstanding the fact that, if not operated on, the largest majority of these infants die within the first year of life.

My experience is at variance with these reports in the literature. Drawing my conclusions from a study of seventy-nine cases of spina bifida that were under my care during the last four years, I propose to demonstrate that with a proper surgical technic and management the mortality may be greatly reduced and that the ultimate prognosis of patients operated on is most favorable.

Studies of operative results in spina bifida commonly fail to distinguish between the results obtained separately in the several varieties of this condition. Spina bifida is a congenital defect and is a result of a malformation of the vertebral arches during the first ten weeks of fetal life, naturally, this malformation may be present in various stages. Clinically it is not important to dwell on the numerous stages that present themselves for consideration. Of interest to the clinician is a discussion of the three main varieties of this disease. The first is the meningocele, a protrusion of the dura through a local defect in the closure of the vertebral arch, the sac being filled with cerebrospinal fluid. When the dual sac contains nerve roots or even the spinal cord itself, which are frequently attached to the sac, it is called myelomeningocele or encephalomeningo-

cele, depending on whether it is situated in the spine or in the cranial region. Finally, when the case presents a splitting or an unfinished closure of a large portion of the vertebral column, it is a rachischisis. While in meningocele the overlying skin is more or less normal in its appearance, the skin overlying the second group is parchment-like thin, frequently broken and occasionally with a sinus draining cerebrospinal fluid. In rachischisis there may be complete absence of any dermal covering, the defect presenting an extensive excavation.

The location in the seventy-nine cases of this study was as follows: occipital, one; occipitocervical, two; cervical, six; dorsal, nine; lumbar, thirty-eight; sacral, sixteen; multiple, three; and cases with a wide splitting of the vertebral column in the lumbosacral region, four. In all there were twenty-six instances of myelomeningocele, forty-four of meningocele, two of occult anterior spina bifida in the sacral region with a myelomeningocele, three of encephalomeningocele, one of these with an additional myelomeningocele in the lumbar region, one of an occult anterior spina bifida in the lumbar region with a myelomeningocele, four of rachischisis, and one of dorsal myelomeningocele with an additional occult sacral spina bifida (fig 1).

Surgical repair was done in sixty cases. The untreated group consisted of four cases of rachischisis, seven cases of myelomeningocele covered with an ulcerated parchment-like membrane with sinuses draining cerebrospinal fluid, three cases of meningocele with a well developed hydrocephalus, and five cases in which operation was refused by the parents. The age at operation of the sixty children ranged between 2 days and $3\frac{1}{2}$ years. Thirty-two children were less than 1 month old, fourteen were between the ages of 1 and 2 months, three between the ages of 2 and 4 months, four between the ages of 4 and 6 months, two between 6 and 9 months, one between 9 and 12 months, two between 1 and 2 years, one $2\frac{1}{2}$ years old, and one $3\frac{1}{2}$ years old.

There were a number of complications in the operated group. A complete or partial paralysis of both legs and of both sphincters was seen in four cases, paralysis of one leg was seen in two cases, paralysis of the urinary sphincter without involvement of the legs was seen in three cases, all with a sacral location of the defect. Complete paralysis of both arms with weakness of both legs was present in a child with a cervical myelomeningocele. Evidence of an incipient hydrocephalus prior to operation was observed in nine cases. In a child aged 1 year, with a lumbar spina bifida, paralysis of the urinary sphincter appeared at the age of 9 months. In one child with a lumbar myelomeningocele, a total paraplegia developed following repeated injections of tincture of iodine into the sac. This "treatment" was kept up for over a year, after which time the child was brought to me.

In all three infants with myelomeningocele died following the operation. This makes a mortality of 14.2 per cent for this clinical variety. The mortality for the entire group being only 5 per cent. The cause of death was infection in all three cases. In two of these, before the child died, hydrocephalus was fully developed. A well marked hydrocephalus was present at the time of the operation in both of these cases, and the wound broke open on the third and the fifth postoperative day. In two of the fatal cases the skin covering the defect was badly ulcerated and infected at the time of operation.

A follow-up of the remaining fifty-seven operative cases shows that one child died of a hydrocephalus eight weeks after the operation and two died of intercurrent diseases three and seven months after the operation, respectively. Eight children were not heard from and the remaining forty-six patients are in a good physical condition. The postoperative periods range between 1 month and 4 years, thirty-seven children were operated on over nine months ago.

OPERATIVE TECHNIC

I am always anxious not to alter the infant's routine before and immediately after the operation. This seems to be most important in very young infants. No change is made in the time of nursing, and weaning the infant from the breast is never made before or soon after the operation.

The anesthesia of choice is chloroform for children during their first year of life, if properly given, it is possible to carry the child smoothly on a surprisingly small amount. Thus is avoided the abundant bronchial secretion and the postoperative profuse perspiration that is seen after ether is used. It is important not to raise the child's head during or soon after the anesthesia.

The infant is placed on the operating table in the prone position with the head at a lower level than the defect. Both legs are abducted, a loop of heavy muslin bandage is placed around the ankles and the bandages are pinned down to the mattress covering the table. The chest, abdomen and both legs are wrapped in warm cotton to prevent loss of body heat during the operation. The operative field is painted with half strength of tincture of iodine and then washed for several minutes with alcohol sponges. At this stage, the anesthesia commences. Towels are attached to the surrounding skin by means of a few stitches of silk. If the summit of the skin covering the spina bifida is ulcerated, it is repainted with full strength of tincture of iodine and covered with an alcohol sponge, which is left until the ulcerated area is freed and removed. This portion of the skin is considered infected and contact with it is avoided at all costs.

The incision is placed in such a way as to save all the available good skin. The skin is dissected away from the underlying sac. To make this dissection easier, additional longitudinal incisions are made. Gradually one approaches the base of the sac, which usually is quite deeply situated. A number of large veins may be encountered there, and all the blood vessels must be clamped before they are divided. It is remarkable how poorly these infants stand loss of blood, a tablespoonful of blood is about all that such an infant will safely stand. When the sac is freed from the surrounding structures it is opened at the summit and carefully inspected. Should the spinal cord and nerve roots be attached to the sac, it is important to mobilize them, since with the further growth of the child and with the migration of the spinal cord upward there may develop a pull on the anchored roots that will result in paralysis.

I had to reoperate on a child six months after the first operation because of a beginning cord bladder. The filum terminale was found adherent to the dura and was under high tension. At the first operation the filum was not disturbed, for it was densely adherent to the sac (fig 2).

The summit which is the thinnest portion of the sac, is resected and the sac closed with closely placed interrupted sutures. I never attempt to return the closed sac to the spinal canal, usually this is impossible to accomplish without pressure on the spinal cord, while in myelomeningocele the spinal canal frequently presents merely a shallow excavation. I now aim to construct a roof over the sac, often this is easily accomplished by means of turning down flaps taken from the deep fascia. The attachment of these fascial flaps to the bony structures bordering the defect is left undisturbed. The flaps are joined without the slightest tension by means of interrupted sutures. I never insist on drawing the erector spinae muscles together over the defect, since this is usually impossible without undue tension.

In cases with extremely wide defects it is not possible to use the deep fascia for a plastic repair, in these I take an additional row of sutures of the sac, invaginating the first row. Thus, I believe, is preferable to a free fascial transplant. A fascial transplant, autogenous or otherwise, is notoriously unreliable in infants, it frequently sloughs and then serves as a medium for an infection. Besides, securing the transplant greatly complicates the surgical procedure. Whenever no fascial plastic operation is possible, I depend on a full thickness of the skin as the only cover. This may require shifting skin flaps, since the skin which originally covered the defect is thin and unsuitable for this purpose. In seven cases of myelomeningocele in which such a repair was made, the ultimate result was good, the original defect, which could be palpated beneath the skin for some time, decreased in size with the growth of the child.

At first I used silk sutures throughout, now I prefer catgut 000 chronic twenty days for all buried sutures, while for the skin I use interrupted sutures of size A silk in fine millinery needles. Buried silk sutures may harbor mild infections for long periods, in two cases, an abscess developed about silk sutures many months after the operation. The skin sutures are removed in forty-eight hours. In the lumbar and sacral regions, the dressing is sealed off from the buttocks. This is best accomplished by protecting the bottom of the dressing with waxed paper sealed to the skin with adhesive tape. The child is removed from the operating table in the prone position with the head lower than the body and is left in this position for the rest of the day. Beginning with the second postoperative day the child may be turned on its side and back. The erect position is not resumed for the first six days. If the temperature remains elevated, the child is kept in the horizontal position even longer. If the suture line becomes red and commences to bulge I immediately aspirate the closed sac, inserting the needle through a point lateral to the incision. Such an aspiration repeated for several days may prevent a threatening sinus formation. However, a bulging of the repaired area is evidence of a mild infection or poor hemostasis, in either case the surgeon must be on his guard to prevent the formation of a sinus. Once a sinus forms, it is important to do everything possible to close it, otherwise it may serve as a portal of entry for infection. Closure of a sinus is frequently accomplished by placing an additional suture through the skin. If drainage of the operative wound is indicated, I place a skin suture, which is left untied until the small rubber tissue drain is removed.

COMMENT

Since the introduction of the classic amputation of the sac in spina bifida, the high operative mortality has been variously ascribed to one or another angle of the operative treatment. Although in the literature the leading causes of death are, in the order of importance, (1) operative shock, (2) infection and meningitis and (3) hydrocephalus, the idea in vogue is that the amputation of the sac is the cause of death through the precipitation of a hydrocephalus. Maintaining that the sac plays an all important role in the absorption of cerebrospinal fluid, Penfield and Cone⁴ recently proposed the operation which is based on a preservation of the entire sac. While there can be no doubt that a hydrocephalus occasionally develops in the wake of a repair of a spina bifida, there is no proof that the amputation of the sac is the cause of it. Experience has shown that whenever the absorption of cerebrospinal fluid is impaired and is barely sufficient to maintain the equilibrium between the production and absorption of the fluid a rapid release of the pressure under which the latter is being absorbed will disturb this equilibrium and precipitate a hydrocephalus. In a patient with a brain tumor with a block of the aqueduct or of the foramen of Monro, tapping of the obstructed portion of the ventricular system will cause a more rapid production of cerebrospinal fluid in it. Aspiration of the sac of the spina bifida leads to an increase in the size of the sac, repeated aspirations will then be required to keep the sac down to its original size.

In fatal cases of spina bifida in which operation has been performed, the hydrocephalus is frequently a terminal condition. It would be of interest to know how many of the children who died with a hydrocephalus following repair were free from a postoperative infection. Even a mild postoperative meningeal infection of a spina bifida may lead to a precipitation of a hydrocephalus. If the sac in spina bifida is an indispensable compensatory organ for the absorption of cerebrospinal fluid, then why are many cases of spina bifida cured by the classic amputation of the sac? The retention of a large portion of the sac during repair is preferred not for its suggested absorptive power but for the fact that it makes feasible less sacrifice and disturbance of the nerve roots attached to the sac. It is also important because the closure of the sac may be done more satisfactorily and with less tension, this in its turn will prevent a leak, an infection and a hydrocephalus.

In the selection of cases for operation it had long been considered that a wide skin defect, as one sees in myelomeningocele with a broad base, is a definite contraindication to surgery. Experience has shown otherwise, plastic repair of the fascia as well as of the skin is successful even in young infants. The prerequisite is prevention of loss of blood. Skin flaps are best taken from above and below the defect rather than from the sides, shifting flaps from the sides may endanger the child's respiration and, besides, the flaps may be disturbed during the child's crying. In two cases of myelomeningocele, repair was carried out in two stages. In the first stage the sac was taken care of and the wide skin defect repaired, four weeks later, the deep fascia was used for the construction of a tent for a better protection of the bulging dura.

⁴ Penfield, Wilder and Cone, William. Spina Bifida and Cranium Bifidum. J. A. M. A. 98: 454 (Feb. 6) 1932.

Paralysis was a leading symptom in eleven instances. One of these cases ended fatally and, with another exception, the child in whom a paraplegia developed following repeated injections elsewhere of tincture of iodine into the sac, the remaining nine patients were either entirely well following the operation or regained function of the paralyzed extremities to a marked degree. This proves the fallacy of the opinion that paralysis is a contraindication to surgery. It seems that paralysis at birth is only a social contraindication to operation, not a surgical one, and the parents' decision to save the child's life even though the child may remain a cripple for life is the one to abide by. Paralysis of the lower extremities or of the bladder, which comes on several months after birth, in the presence of an occult spina bifida or after a repair of a spina bifida is a definite indication for operation, since such a paralysis will readily respond to surgery.

The results that may be achieved with a repair of a spina bifida in a paralyzed child are illustrated by the following example.

CASE 7 (fig 3)—A girl at birth presented an occipital encephalomeningocele and a lumbar myelomeningocele. The occipital protrusion was about one-half the size of the infant's head. The lumbar swelling was the size of the child's fist. When the child was referred to me for treatment, at the age of 4 months, the skin over the occipital protrusion was greatly thinned out and under high tension, the skin over the lumbar swelling, although thinned out, was in good condition. There was some weak movement in the right lower extremity, the left lower extremity was completely paralyzed. The rectal sphincter was dilated and urine dribbled freely from the urethra whenever the child cried. The fontanel was tense and about twice the normal size. The neck was rigid, and slight pressure on the occipital protrusion would cause tonic spasms.

The operation was carried out in two stages. During the first stage, the occipital defect was dealt with. Within the sac, I found the cerebellum which was extremely small. Between the lower poles of the cerebellar lobes the choroid plexus could be distinguished. After ligation and removal of the plexus, the small cerebellum was returned into the cranial cavity. The sac was utilized for the closure of the defect with mattress sutures. Three weeks later, the lumbar defect was taken care of.

The postoperative course was stormy, especially after the repair of the occipital defect. A leak developed which however closed spontaneously ten days later. It is over four years now since the child was operated on. Although her mental development is somewhat retarded, physically she presents a nearly normal child. Her left leg is still somewhat weaker than normal, however she runs and plays without any support.

The time of operation in spina bifida has always been a disputable point. Frazier⁵ is of the opinion that it is best to wait in most cases until the end of the first year of life, this, notwithstanding the fact that his enormous experience has shown that at least 80 per cent of the children die within the first year if untreated. Specular cases of operative treatment a few hours after birth are reported, although the wisdom of it is questionable. If the skin is broken and spinal fluid is draining from the sac it is best to wait until the sinus is healed over. This is best accomplished by protecting the wound with a strip of white silk so as not to disturb epithelization when the dressings are changed. If the skin is not broken one should protect it from trauma and wait until the weight lost by the child after birth is regained, this usually requires about two weeks. If the skin covering the defect is not thinned out there is no paralysis and the sac does not increase in size, one may

well postpone surgical treatment until the child is about 2 months old.

There is a current opinion that a child with a spina bifida shows a mental backwardness in future life. This is a difficult point to prove, since most studies are limited to comparatively small groups of cases. From a detailed follow-up of the cases reported here, I am inclined to believe that a retardation of the mental development of the child is seen only in cases presenting large defects, if the child is submitted to operation late after birth. It seems that the invalid life of the child during its first months retards its future development. There is nothing, however, in this follow-up to show that the average child with a repaired spina bifida is different mentally from normal children.

SUMMARY AND CONCLUSIONS

A study of seventy-nine cases of spina bifida leads to the following conclusions:

Surgical repair is the only treatment of spina bifida. If not operated on, the largest majority of the children die within the first year of life.

The best time for operation varies according to the condition of the skin covering the defect. If there is no break in the skin of the sac, it is best to wait until the weight lost by the child after birth is regained, if there is an ulceration of the skin, with or without free drainage of cerebrospinal fluid, one should wait until the draining sinus is healed, however, if complete rupture of the sac is imminent, operation should be done forthwith.

A broad base of the spina bifida and a wide defect in the vertebral arches are not contraindications to operation.

Paralysis is not a contraindication to surgical treatment, after freeing of the spinal cord and the nerve roots, the child may regain considerable function in the lower extremities and in the sphincters.

The importance of the absorptive power of the dural sac of the spina bifida for the prevention of a hydrocephalus is overestimated, in cases in which a hydrocephalus has ultimately developed, either there was evidence of a beginning of it prior to the operation or it developed in the wake of a postoperative infection.

The operative mortality in spina bifida is greatly reduced as a result of (1) a prevention of loss of body heat during the operation, (2) a prevention of loss of blood, (3) a prevention of rapid loss of spinal fluid, (4) the use of a brief and light anesthesia and (5) the return of the infant to the preoperative routine of feeding immediately after the operation.

ABSTRACT OF DISCUSSION

DR W. JAMES GARDNER, Cleveland: Dr Kolodny's excellent series of results in sixty cases of spina bifida leave few controversial points. A 5 per cent mortality in this type of lesion is certainly a very satisfactory record. I have felt that Dr Penfield's contribution to the treatment of spina bifida—that is the preservation of the sac in order to allow the absorptive area to be preserved—is valuable. Certainly my results have improved very much since I have used his method. Dr Kolodny states that he has adopted the principle in part and saves the lowermost part of the sac, which Penfield points out is the most valuable as far as absorption is concerned. The relation of spina bifida to hydrocephalus is a question that has always intrigued me. The two conditions are closely related and are probably caused by the same congenital defect in many instances. It is probable that in a considerable portion of the

⁵ Frazier, C. H. *Surgery of the Spine and Spinal Cord*. New York: D. Appleton & Co., 1918.

cases the hydrocephalus is the cause of the spina bifida though the spina bifida may be the more obvious lesion. In utero there may be a fusion of the pia and arachnoid membranes which will not permit absorption of the spinal fluid, thus causing an increase in intraspinal and intracranial pressure, which in turn will not permit fusion of the spinal processes. This may be a factor in a fair proportion of cases of spina bifida.

DR HARRY E. MOCK, Chicago. Dr Kolodny has presented an excellent discussion of a condition that is looked on too often by many as a hopeless situation. This paper should serve to rekindle the interest of many surgeons, because now there are possibilities of doing something for it. The contraindications to surgery have been rupture of the sac with meningitis and involvement of the neurologic elements to such an extent that the future of the patient, even with operation, may mean a life of suffering. Dr Kolodny speaks of it as a social rather than a surgical complication. Many mention incontinence of the bladder and rectum as a contraindication to surgery. Dr Kolodny's mortality is much lower than any other I have seen reported and possibly the reason for it is that he has taken a completely paralyzed patient and within from two weeks to two months has boldly gone in and operated. Most surgeons have adopted preservation of the sac. It is the boldness of an early attack that has given the author his good results. Most operators recommend waiting a year.

THE SEX DETERMINATION TEST OF DORN AND SUGARMAN

THEODORE J. CURPHEY, M.D.

AND

ANNE S. ROMER, B.S.

BROOKLYN

This communication proposes to report certain experiments designed at determining the presence of a specific sex hormone in the urine of pregnant women. The experiments were undertaken in an attempt to repeat the work of Dorn and Sugarman,¹ recently reported. These workers found that it was possible to predict correctly the sex of the unborn child in eighty out of eighty-five cases (94 per cent) following intravenous injection of the urine of pregnant women into immature male rabbits. Their predictions were based on the fact that the urine of women who bore female

TABLE 1—Sex Determination Test—Distribution of Animals

Age of Animal	Number of Animals	Size of Injecting Dose
Over 120 days	12	10-30 cc
From 90 to 120 days	17	10-30 cc
Under 90 days	6	10 cc

children caused the testicles of the experimental animals to show enlargement and congestion as well as microscopic evidence of increased spermatogenesis. On the other hand, the urine of women who bore male children caused no such testicular change. In their article they infer that the accuracy of their results was enhanced by the use of animals of a constant breed as they had noted variations in response among their animals depending on such factors as breed, climatic conditions and food. They also state that the factor of age is an important one, as the accuracy of their results depended in large measure on the location of the testicle in relation to the scrotum at the time of the test, the position

of which being related in turn to the age of the animal. It would appear from their article that the age limit is a narrow one, the optimum age for suitable results being between the ages of 90 and 120 days.

With these facts in mind, a study was undertaken in an attempt to repeat the results of these workers. At the outset it was proposed to conduct tests using animals of different age groups injected with various volumes of urine besides those of the stated age group receiving a given quantity of urine, as outlined in the original test. This report deals accordingly with the results obtained with thirty-five male rabbits, varying in age from 80 to 180 days and receiving varying amounts of urine obtained from patients during the last two months of pregnancy. The distribution of the animals in the different age groups is seen from table 1.

TYPE OF ANIMAL USED

The same breed of rabbit² was used in the tests. A strain of New Zealand Whites reared under standard conditions and fed on a constant diet was available. The exact date of birth of each animal was known. Following transfer from the rabbitry and during the period of the test, the animals were kept under the same conditions as to diet.

TECHNICAL METHODS

Of the twelve animals in the group over 120 days, seven received intravenously the larger dose of 30 cc of pregnant urine in three divided doses over a period of eight hours, the remaining five receiving 10 cc in a single injection. Of the seventeen animals in the group from 90 to 120 days, three animals received 30 cc in divided doses, the remaining fourteen receiving 10 cc in a single injection. The group under ninety days all received 10 cc injections. The duration of the test was forty-eight hours, the animals being killed by air embolism at the end of this time and examined immediately. The testicles were exposed and their position in the scrotum was noted. Of the total group, only five showed undescended testicles, four of these being in the age group from 90 to 120 days and one in the group under 90 days. The testicles were then examined as to size and the presence of circulatory changes such as congestion and edema. A cross section was made and an opinion expressed as to the sex of the unborn child. Following this portions of the testicle and epididymis were fixed in 10 per cent neutral solution of formaldehyde and microscopic sections made. Throughout the course of this investigation both the gross and the microscopic diagnosis were made independent of any previous knowledge as to the sex.

The main criteria used in the microscopic examinations were (1) increase in the size of the tubules and (2) increase in the number of spermatogonia and spermatocytes lining the tubules. In addition, cell activity was measured in terms of increase in the size of the nuclear structure with associated increase in their staining qualities. These changes were especially noted in the spermatogonia. In some of the experiments an attempt was also made to measure the degree of cell activity from the changes observed in the epithelial lining of the epididymis. This, however, was soon abandoned, as it became readily evident that cell activity in this organ bore no relationship to similar changes in the testicle. The opinion on the gross testicle was recorded and the microscopic examination

² These animals were obtained from the Thompson Rabbitry, Montclair, N. J. to which we are indebted for the data as to their age.

made without any knowledge of the gross observations. This was done for the purpose of determining the degree of agreement between the two sets of observations.

RESULTS

Animals in the Optimum Age Group—An analysis of the results in which animals within the age limit recommended by Dorn and Sugarman (between 3 and 4 months) were used, arranged according to age in table 2, shows complete agreement between the gross and microscopic prediction and the sex in only two cases (patients M H and K P) of the seventeen (11.8 per cent). On the other hand, there was agreement between the gross prediction and the sex in nine cases (52.9 per cent), while the microscopic prediction agreed with the sex in only six cases (35.3 per cent). It is interesting to note that there was agreement between the gross and microscopic predictions in only six cases, and this irrespective of the sex of the child.

In this age group there were four cases in which the testicles were undescended. These all showed evidence of spermatogenesis microscopically, and in one of these the microscopic prediction was correct. These results

TABLE 2—Sex Determination Test—Animals Between 90 and 120 Days

Patient	Sex of Child	Age of Rabbit	Volume of Urine	Gross Prediction	Microscopic Prediction
M K	Female	3-4 months	10 cc	Male	Female

L H†	Male	97 days	10 cc	Male	Female

* The baby was a stillbirth but the fetal heart was heard two hours prior to delivery.

† Animals with undescended testicles were used.

are not in agreement with those of Dorn and Sugarman, who state that spermatogenesis in response to stimulation with the hypothetic sex hormone is not fully developed until the testicles arrive in the scrotum. Furthermore, this group includes one set of twin males in which the testicles showed microscopic evidence of spermatogenesis and, therefore, led to an erroneous prediction. This animal should not strictly be included in the series, as death occurred within thirty-six hours after injection, but the presence of active spermatogenesis at least indicates cell proliferation in response to the injection of the urine. In this connection it is worthy to note that this patient exhibited symptoms of a mild toxemia prior to delivery.

These results with this group of animals would show, then, that no constant relationship exists between the microscopic evidence of spermatogenesis and sex prediction of the female child. They further show that there is no constant relationship between gross evidence of testicular enlargement and congestion on the one hand and microscopic evidence of spermatogenesis on the other.

Animals in the Younger Age Group—An analysis of a smaller group of younger animals according to

table 3, shows complete agreement in the gross and microscopic prediction with the sex in two of the six animals (33⅓ per cent). There was agreement between the gross prediction and the sex in four of the six animals (66⅔ per cent), while the microscopic prediction agreed with the sex in but two of the six cases (33⅓ per cent), these being the same cases in which there was agreement between the gross and microscopic observations. It is interesting to note that in this group only one of the animals showed undescended testicles, so that, for this breed of rabbit at any rate, it appears as if the testicles begin to descend prior to the latter half of the third month. In patient M O, the urine

was received for examination two days after delivery of a still-born male child. The testicles in this case showed both gross and microscopic evidences of activity which might well suggest the presence of some spermatogenic factor unassociated with sex.

Animals in the Older Age Group—When one considers the older age group of animals, according to table 4, it is seen that there is total agreement between the gross and the microscopic prediction with the sex

TABLE 4—Sex Determination Test—Animals Over 120 Days Old

Patient	Sex of Child	Volume of Urine	Gross Prediction	Microscopic Prediction
T M	Female	10 cc	Male	Female
I W	Female	10 cc	Male	Female
P F	Male	10 cc	Female	Male
R R	Female	20 cc	Male	Male
E H	Female	30 cc	Male	Male
F S	Male	20 cc	Female	Female
B E	Male	20 cc	Female	Male
P D	Female	30 cc	Female	Female
F T	Male	30 cc	Female	Female
E L	Female	30 cc	Female	Male
M A	Female	10 cc	Female	Male
F S	Male	10 cc	Male	Female

in only one case in twelve (8⅓ per cent). The gross prediction agreed with the sex in four of the twelve cases (33⅓ per cent), while the microscopic prediction was in agreement in five of the twelve cases (41.7 per cent). The percentage of error in prediction in this older age group, especially if based on the microscopic observations, is thus not higher than that seen in the more ideally chosen age groups given previously. Moreover, from table 4 it is seen that six of the twelve animals (50 per cent) showed evidence of spermatogenesis irrespective of any relation between this and the prediction of the sex of the unborn child. This number is actually smaller than that of the ideal age group (from 90 to 120 days), as the latter group showed an incidence of thirteen out of seventeen animals (76.5 per cent) exhibiting active spermatogenesis. This would

suggest that natural spermatogenesis in this older group plays but a small part in leading to any confusion as to sex prediction

COMMENT

From an analysis of the results, it is evident that there is no constant agreement whereby the changes excited in the testicle of the rabbit can be used to predict the sex of the unborn child. It further appears that whatever agreement occurs might be readily explainable on the basis of the law of chance. While the number of animals used is relatively small, there are, nevertheless, certain indications that are difficult to dismiss simply on the basis of chance variations within a small group. Thus from the tables it appears that the chances for correct sex prognostication do not necessarily depend on the age of the individual animal. Similarly, there does not seem to be any relationship between what might be described as the action of the spermatogenic factor in the urine of pregnancy and the position of the testicles in the scrotum, as we were able to induce spermatogenesis in animals whose testicles were still intra-abdominally placed.

These results, while offering no support to the view as to the existence of hormones peculiar to each sex, do nevertheless indicate the presence of some agent in certain urines which leads to testicular activity with resulting spermatogenesis. It is barely possible that this activity means nothing more than a quantitative increase of a normally existing substance in the urine of pregnancy. The finding of this spermatogenic factor in the urine of a woman showing symptoms of a mild toxemia (J. W., table 2) points to the need for further investigation as to a possible relationship between this factor and the various toxic states encountered in pregnancy.

CONCLUSIONS

1 Using a pure bred strain of New Zealand white rabbits, we were unable to confirm the observations of Dorn and Sugarmun as to the prediction of sex in the unborn child.

2 The age of the experimental animal and the anatomic location of the testicle at the time of intravenous injection of urine of pregnancy apparently plays no part in the matter of testicular stimulation.

3 There is present in the urine of pregnant women a so-called spermatogenic factor unassociated with the sex of the unborn child.

4 The need exists for a further investigation as to a possible relationship between this spermatogenic factor and toxic states of pregnancy.

480 Herkimer Street

Clinical Science Should Lead—Clinical science should lead the medical sciences of the future as it led in the past. It can do so by waking to full consciousness of its powers and responsibilities. There are many directions in which physiology and animal pathology are fundamental to the study of human pathology. Clinical science, which includes human pathology, is fundamental to the proper pursuit of the healing arts. In this direction it has direct powers of which the remaining medical sciences very rarely become possessed. Because of its immediate and constant bearing on the health of the people, it is the most responsible medical science. But it will be clear that, if it is to take its rightful place in our community, it must acquire full opportunities so that it may be conducted, as are the other sciences, with the freedom of movement essential to vitality, being unhampered by collateral preoccupations and opportunisms. It must be conducted with that rigid adherence to truth that takes no heed of consequences.—Lewis, Thomas. *Clinical Science, Lancet* 2 905 (Oct. 21) 1933.

Clinical Notes, Suggestions and New Instruments

THE GRATEFUL RELIEF OF SCROTAL DROPSY BY THE USE OF A SOUTHEY TUBE

PAUL D. WHITE, M.D., AND JOHN P. MONKS, M.D., Boston

It is well known that in selected cases of intractable and distressing anasarca the insertion of Southey's tubes into the feet and legs may afford much relief and may render more bearable the last few weeks or months of life when there is extensive congestive failure.¹ It is not well known, however, that the most grateful relief of all may be afforded to patients with extensive scrotal edema by the insertion of a Southey tube into the scrotum, as recommended by Southey² himself in 1877. Such a measure is more comfortable and sanitary than incision or simple puncture of the scrotum, since the edema fluid can be easily led off by a small rubber tube into a bottle placed on the floor close to the large chair or the chair bed on which the patient reclines with the head elevated and the legs lowered. As cited in our report on the use of Southey's tubes in 1930, our first patient discharged 1 liter of edema fluid through a tube inserted into the scrotum for a period of twenty-four hours; he lost 15 liters of fluid through other tubes inserted into the legs for twice that length of time.² The rapid relief afforded by the withdrawal of the scrotal edema was more striking even than that resulting from the removal of fluid from the legs. This example has been followed in several instances since then. We are herewith reporting one of these cases because of the record amount of fluid removed from the scrotum and because of the striking relief afforded to the patient in spite of the fact that tubes were not inserted in the legs. To give comfort rather than to prolong a miserable existence was the aim sought in this case.

REPORT OF CASE

G. H. M., a physician aged 79 at the time of his death, had always been well and active until at the age of 72 he strained himself lifting a heavy weight and was laid up for a few days with almost constant dull aching in the anterior part of the chest and the upper part of the abdomen. He recovered his usual good health shortly, but a year later he began to notice dyspnea on exertion. This symptom steadily increased in severity, and at the age of 75 there began to appear nocturnal attacks of orthopnea, frequently associated with asthmatic breathing and infrequently attended by hemoptysis. There also began at that time mild to moderate substernal oppression on exertion, quickly subsiding on resting or taking glyceryl trinitrate. His activity was much limited and he got on fairly well with the dyspneic spells becoming more frequent but less severe. At the age of 77 (January, 1931) slight edema of the ankles began.

Examination at this time, Jan. 19, 1931, showed considerable cardiac enlargement (the apex impulse and left border of dulness were in the sixth intercostal space, 10.5 cm. to the left of the midsternal line), poor first heart sound, slight systolic murmur and protodiastolic gallop rhythm at the apex, accentuated pulmonary second sound, slight left hydrothorax, palpable liver edge (at costal margin), and slight soft edema of both ankles. The pulse rate was 85, the heart rhythm was regular, and the blood pressure registered 135 systolic and 85 diastolic. The electrocardiogram showed normal rhythm, rate 90, inversion of the T waves in leads 1 and 2, and slight widening of the QRS waves (slight intraventricular block) in all leads.

During the next two years dropsy gradually developed, held in check at first by digitalis and mild diuretics. As the edema increased, the frequency and severity of the spells of dyspnea and of substernal oppression decreased. In the fall of 1932, about four months before death, the dropsy increased to a distressing degree and began to involve the scrotum as well as the legs. Early in January, 1933, the intractable edema of the scrotum was causing great distress, the scrotum itself had

¹ Bland, E. F. and White, P. D. The Use of Mechanical Measures in the Treatment of Obstinate Edema. *J. A. M. A.* 95: 1489 (Nov. 15) 1930.

² Southey, R. S. Traitement de l'anasarque general par un drainage capillaire. *Compt. rend. Acad. franç. pour l'avancement des sciences* 6: 826 1877.

enlarged to the size of a small football (60 cm in circumference) January 10, after procaine hydrochloride anesthesia, a Southey tube was inserted into the anterior dependent portion of the distended scrotum. Immediately a stream of fluid gushed out for a few moments. The rubber tubing was then attached and during the next three and one-half hours 1,200 cc drained off into a bottle. The size of the scrotum shrank to that of a large orange (25 cm in circumference) and the patient experienced overwhelming relief. During the next week the scrotum gradually increased in size again but not to what it was before the first tapping. For a second time the Southey tube was inserted into the subcutaneous scrotal edema. In the next twenty-four hours 2,000 cc of fluid drained off, again affording great relief to the patient. During the last nine days of life there was but little reaccumulation of fluid in the scrotum. Death occurred, January 26, from heart failure.

SUMMARY

An elderly physician with intractable and distressing dropsy of the legs and the scrotum was afforded grateful relief by the withdrawal of 1,200 cc and of 2,000 cc of edema fluid through a Southey tube inserted by us into the scrotum on two successive occasions for periods of three and one-half and of twenty-four hours, respectively.

Massachusetts General Hospital

AN UNUSUAL REMISSION IN POLYCYTHEMIA VERA

ERNEST H. FALCONER, M.D., SAN FRANCISCO

In 1918, Dr. S. H. Hurwitz and I¹ reported a case of polycythemia vera in which the patient remained well more than a year following treatment. After five years, the patient still remaining apparently normal, we began to regard her as a clinical cure. In 1923, over six years having elapsed since termination of treatment, she was thoroughly studied with the idea of reporting her case as a clinical cure. She had remained symptom free, with a normal blood level, from late 1916 to 1923. June 16, 1923, the blood count was: hemoglobin 100 per cent (Newcomer), red blood cells, 536 million, white blood cells, 7,400, neutrophils, 74 per cent, eosinophils, 1 per cent, lymphocytes, 20 per cent, monocytes, 5 per cent. About this date a bone marrow biopsy was performed and fatty marrow was found at the site of puncture, the junction of the middle and lower thirds of the right tibia. This finding was against any hyperplasia of the marrow and was evidence, along with the blood count, against any hyperactivity of the erythroblastic portion of the marrow.

In 1927 the patient was again studied and at this time part of her clinical record was included in a published report by Dr. Eugene S. Kilgore.² Dr. Kilgore became interested in this patient when she came to the wards of the University of California Hospital to visit an elderly polycythemic patient under his care. These two people had become acquainted through contact in their work of feather dyeing, suggesting a common etiologic factor for their polycythemia, namely absorption of aniline dyes. Her blood count at the time of this 1927 survey was: hemoglobin 94 per cent, red cells 527 million, white cells, 11,600, neutrophils 69 per cent, lymphocytes 24 per cent, monocytes 5 per cent. Dr. Kilgore felt at this time that the patient was apparently cured mainly through cessation of contact with aniline dyes.

However, Aug. 20, 1928, after twelve years of remission she returned complaining of headache, dizziness, and irregular and excessive menstruation. Physical examination revealed cyanosis of the face, lips, gums, and extremities. The spleen was enlarged and the liver palpable. The blood count was: red cells, 683 million, hemoglobin (Newcomer) 115 per cent, white cells 8,400. The conclusion was that she was now entering the menopause with activation of a latent polycythemia.

Since this date she has been under continuous observation. Her blood level is readily controlled by venesection by irradi-

ation, or by phenylhydrazine given by mouth. The longest interval without treatment has been about eight months. The clinical course for the past five years has been that of a mild polycythemia with few symptoms, with the following exception: Dec. 29, 1929, the patient was having attacks of pain in the right upper quadrant, radiating straight through to the spine posteriorly. About one hour after the pain came on, she became nauseated. Vomiting relieved the pain. The stomach was very irritable after these attacks; she was unable to eat for two or three days, as food caused vomiting. The eyes became bloodshot, there was a bitter taste in the mouth. Examination revealed marked acrocyanosis and cyanosis of the face, lips, and malar eminences. The spleen was palpable. There was no clubbing of the fingers. The liver edge was palpable 3 cm below the costal margin in the upper right quadrant. The edge was moderately tender. There was slight tenderness on pressure over the right upper quadrant, the cardiac rate was slow, with sounds of good quality, no murmurs were heard. The lungs showed no abnormalities. The patient weighed 159 pounds (72 Kg.). The red blood cells numbered 710 million, hemoglobin, 110 per cent, white blood cells 9,350, neutrophils, 67 per cent, lymphocytes, 26 per cent, monocytes, 7 per cent, platelets, 640 thousand, reticulated red cells, 14 per cent. On account of the intense pain and increasing frequency of these attacks, the patient was admitted to the Letterman General Hospital. It was thought that her attacks might be due to chronic cholelithiasis. A gastro-intestinal survey, including gallbladder films following the administration of dye, showed a normal gallbladder visualization and no evidence of gallbladder disease. Gallbladder studies were repeated later with the same results. In collaboration with the officer in charge of her case, I checked the clinical and laboratory data at the hospital, finding only a high blood level, palpable liver and spleen. Roentgen studies, blood chemistry and laboratory data, exclusive of blood counts, were negative. She remained in the hospital one month, taking phenylhydrazine hydrochloride by mouth, 0.1 Gm twice daily for ten days. The attacks disappeared and have not since returned.

COMMENT

This remission of eleven years' duration in a case of polycythemia vera must be unusual as I can find no similar instance in the literature. It is of great interest in that it suggests an important defensive mechanism in the hematopoietic system against factors tending to upset its balance. At present the patient is in the twentieth year of her disease. The general physical status is good, there being no evidence of arteriosclerosis. The heart is not enlarged and there is no evidence of cardiovascular disease. The lungs are normal, there is no evidence of emphysema or pulmonary stasis. The blood pressure is 135 systolic, 95 diastolic.

In view of the possible etiologic significance of dye contact during her work as a feather dyer, the history of her contact with this work has been rechecked. She began work as a feather dyer in 1912. Her work at first was to clean dyed feathers. For this purpose she used a solution of oxalic acid. She thinks her face had a bluish color for a year or more before she began work as a feather dyer. She recalls, at this time, her father remarking about her 'high color' and jokingly asking 'Have you been drinking?' She worked steadily at this establishment for two years, then opened a small place of her own in 1914. In 1913 she had occasional headaches, in 1914 was dizzy, she could scarcely walk, and at that time polycythemia was diagnosed. She remained in the feather dyeing work for fourteen years, leaving it finally in 1926. During 1918 she was away from dye contact for one year.

In view of the fact that the patient was still in contact with dyes during nine years when she was in a remission also, as she has shown continuous evidence of the disease since 1928 with no dye contact, it is unlikely that dye intoxication was a major etiologic factor in her disease. It may have accentuated her polycythemia, early in the course of the disease.

There has been an excellent opportunity here to study a patient with polycythemia vera over a period of many years. It furnishes an interesting commentary on the difficulties of determining the etiology, or of assessing the value of therapeutic procedures in this disease.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS COMPLEMENTING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS IFECH, Secretary

HALIBUT LIVER OIL—*Oleum Hippoglossi*—A fixed oil obtained from the fresh livers of *Hippoglossus hippoglossus*. It is biologically assayed to contain not less than 32,000 units of vitamin A (U. S. P. X) per gram and not less than 200 units of vitamin D (Steenbock) per gram.

Actions and Uses—The same as those for cod liver oil (See General Article Cod Liver Oil and Cod Liver Oil Preparations, New and Nonofficial Remedies, 1933, p. 270).

Dosage—For infants, 6 to 10 drops (25 to 35 minims) daily, for premature and rapidly growing infants, 15 drops (525 minims) daily. For severe vitamin deficiencies, 20 drops (7 minims) or more may be given at the discretion of the physician. The accepted preparations are marketed with an accompanying dropper designed to deliver a certain number of drops to the minim.

Halibut liver oil is a yellow to brownish yellow oily liquid. It has a slightly fishy but not rancid odor and a fishy taste. Halibut liver oil is slightly soluble in alcohol but is soluble in ether, chloroform, benzene, carbon disulfide, and ethyl acetate. The specific gravity is from 0.920 to 0.930 at 25° C. The refractive index is from 1.480 to 1.485 at 20° C.

A solution of 1 drop of the oil in 1 cc. of chloroform when shaken with 1 drop of sulphuric acid acquires a blue color changing to violet dark green and finally brown. Treat 5 cc. of oil with 5 cc. of benzene and centrifuge for twenty-five minutes at 25° C. no precipitate forms and a clear solution remains.

Dissolve 2 Gm. of halibut liver oil in 20 cc. of a mixture of equal volumes of alcohol and ether which previously has been neutralized with tenth normal sodium hydroxide using 5 drops of phenolphthalein T. S. as indicator and titrate with tenth normal sodium hydroxide to the production of a pink color which persists for fifteen seconds not more than 1 cc. of tenth normal sodium hydroxide is required (free acid). The amount of unsaponifiable matter as determined by the method of U. S. P. X page 463 is not less than 7 per cent nor more than 13.5 per cent (it is solid in appearance). The saponification value as determined by the method of U. S. P. X page 457 is not less than 160 and not more than 180. The iodine value is determined by the method of U. S. P. X page 445 on 0.18 to 0.20 Gm. of sample, accurately weighed is not less than 125 and not more than 155.

Abbott's Haliver Oil, Plain—A brand of halibut liver oil—N. N. R.

Manufactured by the Abbott Laboratories, North Chicago, Ill. U. S. patent and trademark applied for.

Abbott's haliver oil plain is prepared by extracting the oil of fresh halibut livers with an organic solvent which is later removed by distillation. The oil is refined and assayed biologically to have the potency of halibut liver oil—N. N. R.

Mead's Halibut Liver Oil—A brand of halibut liver oil—N. N. R.

Manufactured by Mead Johnson & Co., Evansville, Ind. No U. S. patent or trademark.

Mead's halibut liver oil is prepared by warming the livers to coagulation, the extracted oil is filtered, treated with a dilution of alkali and then washed, the entire process being conducted with a substantial exclusion of air. The refined oil is assayed biologically to have the potency of halibut liver oil—N. N. R.

Parke-Davis Haliver Oil, Plain—A brand of halibut liver oil—N. N. R.

Marketed by Parke Davis & Company, Detroit. U. S. patent and trademark applied for.

Parke-Davis haliver oil plain is separated from halibut livers by extraction of cooked livers with sulphuric ether. The ether is removed by distillation. The oil is refined and assayed biologically to have the vitamin potency of halibut liver oil—N. N. R.

Squibb Stabilized Refined Halibut-Liver Oil—A brand of halibut liver oil—N. N. R.

Manufactured by E. R. Squibb & Sons, New York. No U. S. patent or trademark. The use of the antioxidant is covered by U. S. patent 1,745,604 (Feb. 4, 1930, expires 1947).

Squibb stabilized refined halibut liver oil is prepared by extraction from the livers of the halibut. The oil is refined and assayed to have the potency of halibut liver oil—N. N. R. An antioxidant—0.03 per cent of hydroquinone—is added to the finished product as a stabilizing agent.

HALIBUT LIVER OIL WITH VIOSTEROL 250 D—Halibut liver oil to which has been added sufficient viosterol (irradiated ergosterol) to assure a potency of 3,333 vitamin D units (Steenbock) per gram, the halibut liver oil used is adjusted (when necessary) to have a vitamin A potency of not less than 32,000 U. S. P. X units of vitamin A per gram by the addition of fish liver oils from one or more of the species *Gadus morhua*, *Ophiodon elongatus* and *Anoplopoma fimbria*.

Actions and Uses—The same as those for cod liver oil (See General Article, Cod Liver Oil and Cod Liver Oil Preparations, New and Nonofficial Remedies, 1933, p. 270, see also Viosterol, New and Nonofficial Remedies, 1933, p. 427).

Dosage—For infants, 8 to 10 drops (3 to 35 minims) daily, for premature and rapidly growing infants, 15 drops (525 minims) daily, for older children, 15 to 20 drops (525 to 700 minims) daily, for adults, especially nursing and expectant mothers, 20 drops (7 minims) or more daily. The marketed preparation is accompanied by a special dropper designed to deliver a certain number of drops to the minim.

Abbott's Haliver Oil with Viosterol 250-D—A brand of halibut liver oil with viosterol 250-D—N. N. R.

Manufactured by the Abbott Laboratories, North Chicago, Ill. U. S. patent and trademark applied for. The viosterol used is manufactured under U. S. patent 1,680,818 (Aug. 14, 1928, expires 1945) by license of the Wisconsin Alumni Research Foundation.

Soluble Gelatin Capsules Abbott's Haliver Oil with Viosterol 250 D—3 minims. Each capsule contains 3 minims of halibut liver oil with viosterol 250 D diluted with 3 minims of vegetable oil.

Abbott's haliver oil with viosterol 250 D is prepared by combining halibut liver oil one or more other fish liver oils and viosterol in such proportions that the finished product will have the potency of halibut liver oil with viosterol 250-D—N. N. R.

Mead's Halibut Liver Oil with Viosterol 250-D—A brand of halibut liver oil with viosterol 250-D—N. N. R.

Manufactured by Mead Johnson & Co., Evansville, Ind. No U. S. patent or trademark. The viosterol used is manufactured under U. S. patent 1,680,818 (Aug. 14, 1928, expires 1945) under license of the Wisconsin Alumni Research Foundation.

Mead's halibut liver oil with viosterol 250 D is prepared by combining refined halibut liver oil one or more other fish liver oils and viosterol in such proportions as to bring the vitamins A and D potency of the finished product to that of halibut liver oil in viosterol 250-D—N. N. R.

Parke-Davis Haliver Oil with Viosterol 250-D—A brand of halibut liver oil with viosterol 250-D—N. N. R.

Manufactured by Parke Davis & Company, Detroit. U. S. patent and trademark applied for. The viosterol used is manufactured under U. S. patent 1,680,818 (Aug. 14, 1928, expires 1945) by license of the Wisconsin Alumni Research Foundation.

Parke-Davis haliver oil with viosterol 250 D is prepared by combining halibut liver oil one or more other fish liver oils and viosterol in such proportions that the finished product will have the vitamins A and D potency of halibut liver oil with viosterol 250-D—N. N. R.

Squibb Stabilized Refined Halibut-Liver Oil with Viosterol 250 D—A brand of halibut liver oil with viosterol 250-D—N. N. R.

Manufactured by E. R. Squibb & Sons, New York. No U. S. patent or trademark. The viosterol used is manufactured under U. S. patent 1,680,818 (Aug. 14, 1928, expires 1945) by license of the Wisconsin Alumni Research Foundation. The use of the antioxidant is covered by U. S. patent 1,745,604 (Feb. 4, 1930, expires 1947).

Squibb stabilized refined halibut liver oil with viosterol 250 D is prepared by combining halibut liver oil with viosterol in oil in such proportions that the finished product will have the potency of halibut liver oil with viosterol 250-D—N. N. R. An antioxidant—0.03 per cent of hydroquinone—is added to the finished product as a stabilizing agent.

TUBERCULIN-KOCH (See New and Nonofficial Remedies, 1933, p. 377)

Lederle Laboratories, Inc., Pearl River, N. Y.

Tuberculin O. T. (Old Tuberculin)—(See New and Nonofficial Remedies, 1933, p. 379). Also marketed in packages containing 1 cc. of tuberculin.

DIPHTHERIA IMMUNITY TEST (SCHICK TEST) (See New and Nonofficial Remedies, 1933, p. 398)

Hixon Laboratories, Inc., Johnstown, Ohio

Diphtheria Toxin for the Schick Test (Diluted)—A diphtheria toxin prepared by growing diphtheria bacilli in broth, aging and diluting with a solution containing sodium borate 0.36 per cent, boric acid 0.53 per cent and sodium chloride 0.61 per cent. The diluted toxin is of such strength that 0.1 cc. (one dose) given intracutaneously constitutes one-fiftieth minimum lethal dose for a guinea pig of 250 Gm. weight. The product as marketed is ready for use, no diluent being required. Merthiolate 1:10,000 is used as preservative. Marketed in packages containing sufficient material for ten, twenty-five and fifty tests.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

Special Articles**THE HEALTH HAZARD OF AMEBIC DYSENTERY**

REPORT OF AN OUTBREAK

HERMAN N. BUNDESEN, M.D., Sc.D.

President Chicago Board of Health

ISAAC D. RAWLINGS, M.D.

AND

WILLIAM I. FISHBEIN, M.D.
CHICAGO

An outbreak of amebic dysentery among employees and guests of several hotels and eating establishments in Chicago became manifest in August. Practically all of the guests were nonresidents of Chicago and as a result the disorder spread to other cities. This preliminary report is being published therefore, to describe the epidemic and the measures instituted to control it. Physicians throughout the country should be on the lookout for cases of the disease.

Authorities¹ state that from 8 to 10 per cent of the population as a whole are infected with *Endamoeba histolytica*. The rate is probably not quite so high in Chicago. However, many of these infected persons do not have symptoms of sufficient severity to indicate that they are infected. While these chronic or carrier patients may not suffer from ill effects, they are a menace to others. This is well borne out by the present outbreak of amebic dysentery.

Until August 1933, one or two cases of amebic dysentery were reported each month in Chicago. This is the usual level, as is demonstrated in table 1, and was no cause for alarm.

TABLE 1—Cases of Amebic Dysentery by Months from January 1930 to Oct. 15, 1933

Year	January	February	March	April	May	June	July	August	September	October	November	December	Total
1930	1	2	0	0	0	0	1	0	0	0	0	0	3
1931	1	2	0	0	0	0	1	0	0	0	0	0	4
1932	1	2	0	1	2	2	2	2	4	2	0	0	17
1933	0	1	2	0	2	2	2	12	14	22	0	0	53

On August 15, two cases were reported, one each by a hospital at which the patients were being treated. These cases were investigated. It was found that both patients had eaten at a certain hotel in Chicago. An investigation was immediately ordered and a staff sent to the hotel for the purpose. Investigations were made of the entire group of food handlers at the hotel and thirteen clinical cases of amebic dysentery were discovered by the end of August.

Control measures were established immediately. These included:

1. The prompt isolation and treatment of all cases and carriers.
2. Stringent sanitation in toilets in regard to washing the hands.
3. The prohibition of food handlers with stools positive for *Endamoeba histolytica* from returning to their work after treatment until they had had three negative specimens of feces taken at intervals of one week.

¹ Johnstone, H. G., David, N. A., and Reed, A. C., A Protozoal Survey of One Thousand Prisoners, J. A. M. A. 100:728 (March 11), 1933.
² Craig, C. F., The Amebiasis Problem, ibid. 98:1615 (May 7), 1932.

The University of Chicago cooperated in carrying out the laboratory work necessary.

Specimens of feces were collected and examined in warm distilled water and stained with iodine. The following technic was employed:

A drop of physiologic solution of sodium chloride and one of iodine stain were placed close together on a slide, but not touching. A round applicator stick or a tooth-pick was smeared with the feces and was rolled in the drop of salt solution and then in the drop of iodine solution. A single cover slip was placed on both drops, half of the material under it being stained and the other half unstained. The unstained portion was first examined for living flagellates and active amebas. In the stained portion the protozoan cysts stood out as bright spheres against the pink background and soon became tinged with the iodine to varying tones of yellow. The nuclei became clearly defined as the iodine penetrated.

The iodine reagent was prepared from a 5 per cent aqueous solution of potassium iodide, saturated with iodine, which was then diluted with an equal amount of distilled water.

Of 364 food handlers from the hotel who were examined up to September 1, fifteen active cases and eleven carriers were found. A preliminary report of this was made, October 9, by Fred O. Tonney, Gerald L. Hoeft and Bertha Kaplan Spector,² before the Laboratory Section of the American Public Health Association in Indianapolis.

As soon as a person was found to be harboring the ameba within his intestinal tract, he was excluded from the hotel.

Later, on October 25, a second examination was made of all the food handlers of the hotels as well as of the non-food handlers. On the second examination, feces were obtained from all of the food handlers previously examined except the twenty-six who had been excluded.

It was found that 60 had *Endamoeba histolytica* in the stools who were negative on the first examination, 498 non-food handlers were examined and 100 were found to have *Endamoeba histolytica* in the stools. In this second laboratory survey, which was extended to include all the employees of the hotels, carriers of the parasite were found by using cultural methods. Of these, 23 were among food handlers and 23 among other employees. These carriers had not been discovered when the only tests made were direct microscopic examinations of the specimens of feces.

A liver infusion agar was used for making the cultures. A pea size lump of feces was added to a slant of the warm liver infusion agar and dilute serum (one part of serum to six parts of sterile physiologic solution of sodium chloride).

The following are the directions for making liver infusion:

1 pound of fat-free ground beef liver, 500 cc of tap water in a covered pail. Put in flowing steam for twenty minutes. Stir. Boil one and one-half hours longer in an Arnold sterilizer, stirring continually. Filter through a wire screen. Sterilize.

From this the liver infusion agar is made as follows: 500 cc of liver infusion, 500 cc of tap water, 20 Gm of washed agar, 10 Gm of peptone, 5 Gm of sodium chloride. Arnoldize the foregoing for thirty minutes. Cool to 60 C. Adjust to pH 7.

² Tonney, F. O., Hoeft, G. L., and Spector, Bertha Kaplan, Threat of Amebiasis in the Food Handler, this issue, p. 1638.

Arnoldize for one and one-half hours Tube or put up in flasks Autoclave at 15 pounds for thirty minutes

The cultures are examined for *Endamoeba* after twenty-four and forty-eight hours' incubation at 37 C

Thus far in Chicago there have been 19 deaths from amebic dysentery and 185 cases of the disease and 193 carriers of *Endamoeba histolytica* traced in this outbreak. It is impossible to state just how long the infestation had existed among the employees of these hotels

DIFFICULTIES IN CHECKING THE OUTBREAK

Like other infections with protozoa, those with *Endamoeba* produce a variety of symptoms. The disorder may be fatal in a short time, it may be severe for a long or a short period. The disorder may become chronic with alternating periods of diarrhea and constipation. It may be mild and cause little discomfort. In addition, the incubation period of the disease varies from nine to ninety-five days.

The great majority of the persons patronizing the hotels were not residents of Chicago. Frequently, those infected had returned to their homes in some distant city before symptoms became apparent. Consequently, it was decided to send a questionnaire to the out-of-town guests of the hotel chiefly concerned. The probable date of the outbreak seemed to be about May 1, 1933. Therefore, the questionnaires were sent to all individuals who had registered after that date. Of 22,000 questionnaires sent out, approximately 200 were returned because of the wrong address. Up to November 14, approximately 3,490 replies had been received.

In the questionnaire, information was requested as to any illness occurring during or after a visit to Chicago. Of 3,490 questionnaires 180 reported illnesses. Of these, 69 were positively diagnosed as amebic dysentery, 23 were reported as suspected of having amebic dysentery, and 88 were reported as having disorders other than amebic dysentery. Among the disorders listed were ulcerative colitis, mucous colitis and appendicitis. Many of the persons suspected of having an amebic infection had bloody stools and diarrhea. All of the individuals had outbreaks of diarrhea eighteen days or more after they had eaten at the hotels or restaurants from which the outbreaks were traced.

Table 2 shows the number of cases occurring in various cities in which a diagnosis was definitely made by laboratory methods. All of these individuals gave a history of having eaten at the hotels and later developing amebic dysentery.

Dr Charles C Lund of Boston writes that six members of a committee which met in Chicago, June 30, developed colitis. Four of them died. Three of the deaths have been definitely found to be due to *Endamoeba histolytica* infection. He adds "Apparently sporadic cases of amebic dysentery fall into the hands of excellent doctors, but doctors who are inexperienced in the diagnosis and treatment of the disorder. The diagnoses are mostly missed and many of them have surgical operations which result unfortunately."

Amebic dysentery is the cause of many obscure intestinal disorders. Many cases are unrecognized, but these cases act as foci from which the disease is spread throughout the country. Physicians having cases of diarrhea in which the cause has not been discovered should have repeated examinations of the stools made. It will aid greatly if the Chicago Board of Health is

notified of all positive cases that seem to have emanated from Chicago. The board is anxious to cooperate in checking the spread of the disease.

A great deal of the spread is undoubtedly due to carriers engaged in food handling. These food handlers act as foci from which the disease is spread. These foci will remain unrecognized unless routine stool examinations of all food handlers are instituted.

All food handlers who have a history of amebiasis should be examined once a month for four months and thereafter every six months for the rest of their lives. This is advocated because two of the food handlers discovered to be harboring the ameba in this outbreak were also carriers of ameba in 1927 and were discovered during an outbreak of amebic dysentery in Chicago at that time.³ Repeated stool examinations were negative for the ameba for many months in these two persons but the organisms reappeared years later.

To Nov 14 1933

Surveys made in Chicago and areas farther north¹ show that amebic dysentery is not a particularly uncommon disease. Williamson and Geiger⁴ reported the examination of 148 persons in 1929, all of whom were food handlers, and found that 27 were carriers of ameba and 2 were actively infected.

Between 1921 and 1927 there were thirty-three deaths from amebic dysentery in Chicago. S J Lewis⁵ stated that infection with *Endamoeba histolytica* is more prevalent than once thought. It is especially common in the southern parts of the United States.⁶ The outbreaks of it that occur are in many cases the result of infection transmitted by carriers of *Endamoeba histolytica* who are engaged in food handling.

All food handlers should be carefully examined and reexamined and specimens of feces studied for the presence of the parasite. From three to six stool examinations should be made on every individual suspected of having amebic dysentery. In all cases of diarrhea

or chronic intestinal disorders, a careful search of the stools should be made for the presence of *Endamoeba histolytica*. Amebic dysentery is a real health hazard. It demands the attention of health officers.

THE THREAT OF AMEBIASIS IN THE FOOD HANDLER

FRED O. TONNEY, MD
GERALD L. HOEFT, VMD
AND

BERTHA KAPLAN SPECTOR, PHD
CHICAGO

In the light of the very disquieting experience here recounted, which is the second of its kind occurring in a large metropolitan center within a few years, one clearly defined fact is apparent—that too little thought has been given to amebiasis as a public health hazard in the United States.

Although several published surveys,¹ have called attention to the growing incidence of infestation with *Endamoeba histolytica* in this country, giving evidence that from 3 to 10 per cent of the populations studied were infested with this parasite, the general impression still prevails that the disease is mostly confined to tropical and subtropical regions and is of little concern in the temperate zones.

However, two recent outbreaks of amebic dysentery in large urban hotels—the last numbering thirty-one clinically active cases and eleven carriers of the encysted parasite at the time of the first examination, with a number of unexplained cases in the city at large—should serve to reawaken interest in this growing danger to the public health, and help to correct the current medical point of view.

SOURCE OF THE DISEASE

The epidemiologic factors that have brought amebiasis to the United States, though published from a number of sources will nevertheless bear repetition.

The importation of and immigration to this country of peoples from areas in which the infestation is endemic, viz., the Negro, the races of southern Europe and Asia—Italians, Greeks, Turks, Syrians—the Mexican, the native of the West Indies and of South America, and similar racial extractions. This step in the process of infestation is now history. It occurred several generations ago.

Travel on the part of many of our people to regions where amebiasis is endemic, and whence some return infested.

Possibly the growing consumption of raw fruits and vegetables, some of which come from regions infested with amebas, such as California, Mexico, Tennessee, Florida and, in fact, most of the Southern states.

The stress of economic conditions, leading to the employment of cheap labor in the kitchens of the large urban hostels and food dispensing establishments, labor too often recruited from these infested areas.

A lack of a proper sense of personal cleanliness among food handlers and, again, not least in importance, lack of facilities for personal cleanliness and lack of the psychology of cleanliness in the kitchens.

Read Oct. 9, 1933 before the Laboratory Section of the American Public Health Association at its sixty-second annual convention in Indianapolis.

From the Section of Technical Service and Research, Chicago Board of Health, and the Douglas Smith Foundation of the Department of Medicine, University of Chicago.

Intestinal Parasites in Overseas and Home Service Troops of the U. S. Army. J. A. M. A. 73: 1721 (June 14), 1919. Craig, C. F. The Amebiasis Problem. J. A. M. A. 98: 1615 (May 7), 1932. Johnstone, H. G., David, M. A., and Reed, A. C. A Protozoal Survey of One Thousand Persons. J. A. M. A. 100: 728 (March 11), 1933.

PRESENT MODES OF SPREAD

Infestation with *Endamoeba histolytica* in this country usually implies the taking of food or drink that is contaminated with the bowel discharges in a case or carrier harboring the cysts of the parasite. Modern sanitation virtually precludes the general transmission of amebiasis by public water supplies and milk supplies. The transfer is accomplished mostly through food handlers. The latter were obviously responsible for the two recent outbreaks to which reference has been made.

The first warning of trouble came in 1927, when "seven or eight cases" were traced to a large hotel. The second outbreak here reported began in June, 1933 and up to September 1 comprised forty-two cases and carriers in another urban hotel. Suspicion had been directed to this hostelry by the occurrence in the city of several cases of amebic dysentery in persons who had been guests of the hotel.

PROCEDURE

With the cooperation of the management, the entire food handling personnel of the hostelry was examined by representatives of the laboratories of the board of health. A room with bath in the hotel was secured and equipped for the necessary laboratory examinations. A list of the food handling personnel was obtained and each person was ordered to report to the examination room. Here, specimens of feces were collected in half-pint paraffined cardboard containers and examined immediately.

Two or more preparations were made from each specimen, one mounted in warm distilled water, and the other stained with iodine.² The fresh preparation served primarily to demonstrate the active amebas, although encysted forms could also be seen. The iodine-stained preparation permitted differentiation of the cysts from other related forms, by a study of their cytology. When the specimens of feces were found to contain suggestive bodies, more smears were made, and these were always examined by two or more technicians. An additional specimen was procured whenever the first test proved unsatisfactory.

RESULTS

Of 364 food handlers examined up to Sept. 1, 1933, fifteen clinically active cases and eleven carriers of the cysts were found. These included five cooks, one sauce maker, one cold meat man, one baker, two butchers, five dishwashers, two counter girls, one waffle girl, seven waiters and one pantry boy. In addition, five other clinical cases were reported among employees not engaged in food handling, while eleven more clinical cases occurred among the guests or diners at the hotel. There was rather clear evidence of an outbreak of amebic dysentery during June, July and August, 1933.

EPIDEMIOLOGY

Quite evidently, then, amebiasis had become widespread among the kitchen help of this establishment at some time since 1927 when the former investigation was made, the exact origin of which cannot now be definitely established. However, the epidemiologic possibilities are most interesting. With such appropriate foci infested as a "sauce maker," and a "cold meat cutter," together with twenty-four others throughout the kitchen personnel, it is easy to understand the

2. Kaplan, Bertha, Williamson, C. S., and Geiger, J. C. Amebic Dysentery in Chicago. J. A. M. A. 88: 977 (March 26), 1927.
3. The stain consisted of a 5 per cent aqueous solution of potassium iodide saturated with iodine which was then diluted with an equal amount of distilled water.

probable extent of the secondary cases that may have occurred among the guests, most of whom were transient visitors to the city.

As to the primary origin of the outbreak one case in particular offers a plausible explanation. This man, a baker, was the only person who gave a definite history of having been previously infested. He had been found to be a carrier of *Endamoeba histolytica* in 1927, in the previous investigation by Kaplan, Williamson and Geiger.² At that time he was employed in another hotel. He was given a thorough course of treatment in a university hospital and after many negative laboratory tests was finally permitted to resume his occupation as a food handler. Now he is found again in the midst of another outbreak. Of course he may have been reinfested, but it seems most likely that his was a recurrent case. Frankly, we do not know what his relation may have been to the latest outbreak. But should not thought be given to the wisdom of permitting any such person, once found to be a carrier of *Endamoeba histolytica*, to resume work as a food handler, even though he may have had a most exacting course of treatment in the most competent hands?

EMERGENCY CONTROL MEASURES

The immediate measures adopted for control of the outbreak were

- 1 Prompt isolation and treatment of all cases and carriers found among the food-handling personnel
- 2 The promulgation of stringent hand washing and disinfecting regulations, with monitors posted in the toilets adjacent to the kitchens to see that these rules were carried out
- 3 The placing of placards bearing an order to wash and disinfect the hands, in all nearby toilets used by employees
- 4 Increasing the hand washing conveniences by installing additional wash bowls throughout the kitchen quarters
- 5 General cleaning and painting of the kitchens, pantries and store rooms in the entire plant, to promote the psychology of cleanliness

REGULATIONS

Tentative regulations were also drawn under which food handlers might be permitted to resume their occupation after a suitable course of treatment.

Food handlers, after treatment for amebiasis and before being permitted to resume work, must have at least three successive negative specimens of freshly voided feces, taken at intervals of one week—the last two of which must be examined by the board of health laboratories.

The laboratory procedure recommended is

- (a) A direct microscopic examination of a warm water preparation
- (b) A direct microscopic examination of an iodine-stained preparation
- (c) Examination of a fixed smear, stained with iron hematoxylin, for differentiation of doubtful encysted forms, and also for a permanent record of the observations
- (d) A culture on a suitable medium.⁴

It is recommended further that all food handlers having a history of amebiasis be examined once a month for four months and thereafter every six months while working as food handlers.

SUMMARY AND CONCLUSIONS

Sixteen clinical cases and eleven carriers of the encysted *Endamoeba histolytica* were found among 364

food handlers examined up to Sept. 1, 1933, in a large hostelry. Five clinical cases had also been reported in other employees not engaged in food handling, and eleven clinical cases among the guests and diners.

The effort to control the outbreak consisted of exclusion of the infested food handlers from the kitchens and rigid application of appropriate sanitary measures.⁶

The indications point to an old carrier, previously detected in 1927, as the most plausible primary source of the outbreak. Proof of this, however, is necessarily lacking, and there were several other plausible possibilities of causative agents among the food handling personnel.

The danger of recurrence of the infestation, even after most thorough and competent treatment, is emphasized in the case of the employee mentioned, who was associated with a previous outbreak in 1927.

It is recommended that food handlers who are known to have suffered from amebiasis be required to submit specimens of excreta every six months for examination by an approved public health laboratory, as long as they continue to work as food handlers.

The incident reported is a striking illustration of the constant need of well equipped research laboratories in modern public health organizations—laboratories liberally manned by a well trained technical personnel, which can be drafted at a moment's notice for such emergencies as this and which in the meantime can be kept permanently and profitably occupied with a study of improved methods of conserving human life and health.

AMEBIC DYSENTERY

A REVIEW

NOTE—The following article is compiled from a number of textbooks and periodicals in order that physicians may be aware of current knowledge regarding this disease. The development of the disease in a Chicago hotel and the occurrence of numerous cases throughout the United States indicate the desirability that physicians be fully informed concerning the symptomatology, differential diagnosis and treatment of amebic dysentery.—ED

Amebic dysentery, also called amebic colitis and enteritis, refers to infection of man by a protozoan parasite, *Endamoeba histolytica*. Originally considered a tropical disease, the infection is now frequently observed in the temperate zones. There are numerous carriers of the infection, and it has been estimated that from 5 to 10 per cent of the population may have the organism in their intestines. However there seem to be variations in the infectiousness of the condition at various times, so that apparently certain epidemics may carry greater intensity of the infection and higher morbidity and mortality than others.

When the ameba invades the intestine it burrows under the submucous coat and produces its harmful effects by destroying the tissue with which it is in contact. Cytolytic and hemolytic substances, according to Craig¹ have been extracted from cultures of the

⁵ Continued observation of this focus of infection has served to reemphasize the necessity of examining such groups of food handlers several times in order to detect all those harboring *Endamoeba histolytica*. Evidently the parasite is not discharged regularly in sufficient number for certain detection by the laboratory methods thus far available. The use of cultures in addition to the direct microscopic examination has definitely proved its value in our hands. An interval between the laboratory examinations of such groups seems desirable to permit the development of incubative cases and to aid in the detection of those who apparently discharge the parasite intermittently.

¹ Craig C. F. Amebiasis in *Musser Practice of Medicine* 1932 p. 341. Other articles that may be consulted include Simon S. K. Amebic Dysentery in *Tice Practice of Medicine* 1927 p. 271. Strong R. P. Amebiasis in *Nelson's New Loose Leaf Medicine* 1932 vol. 2 p. 331. Sellards A. W. Amebic Dysentery in *Cecil Textbook of Medicine* 1933 p. 396.

⁴ A culture medium found satisfactory for growth of *Endamoeba histolytica* is a liver infusion agar medium prepared as described by Huddleson Halsey and Torrey (J. Infect. Dis. 40:382 [Feb.] 1927). Slants are made from this medium and just prior to the inoculation are covered with sterile inactivated sheep or horse serum diluted with six parts of sterile saline solution.

organism. In the tissue of the intestine and under favorable conditions in the lumen of the intestine itself the ameba may divide into two daughter amebas, and this multiplication continues indefinitely until conditions unfavorable to further growth develop. Then the amebas become round, lose their motility and form cysts, which are covered with a cyst wall. These cysts are excreted in the feces and act as infective agents. The active stage of the ameba cannot pass through the stomach and live, as the hydrochloric acid of the gastric juice destroys the organism.

However, the cysts when taken into the body in food or in fluids break up in the lower part of the small intestine. Each cyst liberates a single ameba containing four nuclei. These nuclei again divide, producing eight, and then the parent organism divides into eight small amebulae, which develop into the form that causes the pathologic condition. The cysts when passed out of the body are resistant to various chemical agents and may live for weeks in water or in fecal material that is kept moist and in the shade. Living cysts have been found in the excrement of flies thirty-six hours after the flies have fed on infected feces. The cysts are destroyed by sunlight and by drying.

In the vast majority of cases, human beings are infected through food or water contaminated with the cysts. Such contamination occurs through the use of sewage for fertilizing vegetables, through flies and through contaminated water, but primarily in this country by contamination through food handlers who are carriers of the parasites.

SYMPTOMS

When a human being is infected with the ameba, he may develop an acute condition. He may be for a while without symptoms and eventually may develop a chronic condition. In acute amebic dysentery, the onset is usually sudden. There is severe pain in the abdomen, which is followed by an intense desire to defecate. The pain over the abdomen is severe. There may be vomiting and nausea although these are not most frequently reported. The diarrhea is exceedingly serious, beginning with from fifteen to twenty movements during twenty-four hours, and in some cases there may be from thirty to thirty-five. The first material passed contains mucus, but soon the stools are largely fluid in character, containing mucus, blood and shreds of mucous membrane. Tenesmus is severe, and the patient soon becomes weak and greatly depressed. Fever is rather infrequent but there may be slight fever proceeding to a rise in temperature associated with a diarrheal condition or with collapse.

In the majority of cases, these conditions persist for three or four days and then clear up, to be followed by further mild attacks from time to time. In some of these cases, chronic amebic dysentery supervenes. There is also in many instances an infection with bacillary dysentery superimposed on the amebic form of infection.

The tenesmus may be so severe that the patient must be almost constantly on the bed pan. In most cases the abdominal wall is retracted and rigid and exceedingly sensitive to the touch. Because of the tendency of the tenderness to localize in the right iliac region, cases are frequently mistaken for appendicitis. If the case is severe and long continued, the patient becomes emaciated and weak and may have jaundice and all the symptoms usually associated with chronic intestinal infection of this character.

If the condition becomes chronic there are repeated attacks of colic and diarrhea, loss of appetite, and the appearance of blood and mucus in the stools. Between attacks the health may be such as to permit the patient to work, but there are usually loss of appetite, disturbance of sleep, and other symptoms indicating the presence of the disease. Such cases have been reported to continue for years, eventually leading to a condition of chronic invalidism. Between the acute attacks there may be soreness over the abdomen, but otherwise physical signs are not noticeable.

DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS

In the presence of an epidemic, a physician should, of course, be alert for the possibility of this disease in all forms of diarrhea, but particularly when the history of the patient indicates a possible contact with a carrier of the ameba. The typical attack of amebic dysentery may be diagnosed by an experienced diagnostician. In many of the cases, however, that have been occurring in connection with the recent epidemic the diagnosis is overlooked because the physician did not suspect the possibility.

Cases of amebiasis have been mistaken for bacillary dysentery, mucous colitis, ulcerative colitis, appendicitis, peritonitis and other disorders. The conclusive diagnosis is, of course, dependent on the finding of the organism in the stools. Moreover, it must be remembered that symbiotic infection with amebic dysentery and bacillary dysentery may occur. The majority of patients suffering with amebic dysentery are ambulatory. It may be possible for the physician to secure specimens of stools on which examination may be made, in other instances it may be necessary to use the proctoscope or the rectal tube in order to secure specimens for study. Furthermore, it may be necessary to examine several specimens of the stool in order to determine the presence of the ameba.

In the examinations made in the infested hotel in Chicago in connection with the present epidemic, as shown by the paper by Tonney, Hoeft and Spector in this issue, repeated examinations revealed in each instance that certain persons were carriers. In searching for cysts the more solid particles of feces are selected and diluted with physiologic solution of sodium chloride to form a thin smear. The nuclei lie at different levels so that careful focusing is necessary in order to distinguish their structure. Compound solution of cresol of double strength is sometimes used for staining the nuclei. When good laboratory facilities are available, specimens may be taken for immediate examination by a competent laboratory investigator. There are numerous special stains and fixation methods of aid in the determination of the presence of the ameba.

COMPLICATIONS

The complications of a more serious character are those related to the formation of abscesses in the liver and in various other organs of the body.

PROGNOSIS

Sellards says that approximately one third of the early cases are cured by a single complete course of emetine. Patients who relapse have a good outlook for recovery if the relapses are treated persistently and thoroughly. If, however, there is extensive secondary bacterial infection the patient may have difficulty in recovering his health.

TREATMENT

In the treatment of acute amebic dysentery, Charles F. Craig recommends particularly the use of emetine, as emetine hydrochloride or emetine bismuth iodide. "Emetine is a specific," he says, "so far as relief of symptoms is concerned, the patient being well on the road to a symptomatic recovery within the first few days after beginning treatment, but it is doubtful if it actually cures more than one third of the cases treated, even if repeated courses are administered. This drug finds its greatest field of usefulness in the treatment of the acute symptoms which disappear rapidly under its administration. It is best given orally or subcutaneously, and never intramuscularly or intravenously. When given by mouth, keratin-coated pills or capsules should be used, and not more than 0.1 Gm (1½ grains) should be given morning and evening in equally divided doses. The drug is seldom used alone by mouth, but the oral and subcutaneous methods are combined, 0.03 Gm (one-half grain) being given by mouth every evening, and 0.065 Gm (1 grain) subcutaneously every morning, for ten or twelve consecutive days. The oral administration is often entirely omitted and 0.065 Gm (1 grain) of emetine given daily for twelve days in cases that are not considered unusually severe. The treatment is repeated if relapses occur. Emetine is a toxic drug and, when given in too large a dose or over too long a period, causes severe diarrhea, myocarditis, neuritis, nervous prostration and great muscular weakness, and death may occur suddenly from cardiac failure. Such symptoms should be carefully watched for and, if they appear, the drug should be discontinued at once. During the treatment the patient must be kept in bed.

"Chiniofon is administered orally and by enema in the treatment of acute amebic dysentery. For an adult the course of treatment consists in the oral administration of 1 Gm (15 grains) three times a day for eight to ten days, interrupted for a week to ten days, and the same dosage repeated. Severe diarrhea may be caused by the recommended dosage and, if so, the dose should be reduced one half. To secure the best results with this drug, the use of enemas containing chiniofon should be combined with the oral treatment. If this is done, 0.5 Gm (7½ grains) of chiniofon should be administered three times a day by mouth and a daily enema should be given of 200 cc of a 2 per cent warm water solution of chiniofon, which should be retained for several hours. The treatment should be continued for ten days. If the full dose of 1 Gm of chiniofon three times a day is given, combined with the enemas, severe diarrhea is very apt to occur, and the results obtained with the smaller dosage are apparently as good. Throughout the treatment the patient must remain in bed. Chiniofon is a less toxic drug than either emetine or emetine bismuth iodide, and is apparently more efficient in curing amebic infections."

In the chronic cases Craig recommends continuous treatment with emetine bismuth iodide or chiniofon. He also points out that the condition is long standing, relapses frequently occur and the prospect of complete cure with any known method of treatment is poor.

Acetarsone has been used in the treatment of acute amebic dysentery and excellent results are reported, but Craig believes that emetine or emetine bismuth iodide should be used first and this followed with

acetarsone in case the patient becomes a carrier. Acetarsone is given in this condition in doses of 0.25 Gm in tablet form three times daily by mouth for one week only. After an interval of one week or ten days a second course may be given if the amebas persist.

It must be remembered that the margin between the toxic and the therapeutic doses of emetine is small. Because of the danger of poisons as manifested by increase in the pulse rate, loss of weight or peripheral neuritis, the physician must give the product with care.

Drs. N. A. David, A. C. Reed and C. D. Leake have used a product related to chiniofon, known as iodo-chloroxyquinoline (vioform N. N. R.). This product is given in a dose of 0.75 Gm by mouth in gelatin capsules daily for ten days, with a repetition of the course of treatment after a week's rest period. A total of 15 Gm is thus given in about a month's time. Thirty-nine out of forty-seven cases of human amebiasis were cleared of *Endamoeba histolytica* in the stools on repeated examination over a period of four months after treatment was stopped. Amebiasis recurred in the stools of five patients within two months after treatment was stopped but were eradicated by repetition of the treatment. Three very severe cases could not be cleared. The authors report that the total dose of the drug administered did not exceed 600 mg per kilogram in any one case, and in no case was any evidence of toxicity observed. In their report they believe that vioform is the most efficient drug of any type used in amebiasis.

Carbarsone was used in chronic amebiasis with the dosage of 250 mg in gelatin capsules twice daily for ten days. Of thirty-three patients who had stool examinations at daily intervals for three months after cessation of treatment, the stools were free of *Endamoeba histolytica* in thirty cases, with prompt relief from symptoms and general improvement in physical condition and without any untoward effects.

So far as concerns general treatment, Craig says: "Confinement to bed is necessary in patients suffering from acute dysentery or acute exacerbations of the chronic type. A proper diet is of great importance and the smaller the amount of food taken while there are acute symptoms, with due regard to conserving strength, the better. During acute symptoms the diet should consist of broths, barley water, egg albumin, and milk with lime water. Pure milk or malted milk may be used when the acute symptoms improve and eggs, soft puddings and a semifluid diet should be given after the subsidence of the acute symptoms. A full diet is gradually adopted during convalescence, care being taken to avoid foods that are known to irritate the intestine. Alcohol should be forbidden in all cases of amebiasis, especially in those presenting dysenteric symptoms, and even in 'carriers' indulgence in alcoholic stimulants frequently results in the appearance of symptoms, while in the chronic amebic dysentery patient alcoholic indulgence is often followed by a relapse of the dysenteric condition. The use of tonics during convalescence is indicated."

The cure of amebiasis can be determined only by the permanent disappearance of the amebas from the feces, and every treated case should have repeated examinations of the feces for a period of at least four months after the cessation of treatment. If trophozoites or cysts reappear treatment should be repeated."

SATURDAY, NOVEMBER 18, 1933

THE AMEBIC DYSENTERY EPIDEMIC

Elsewhere in this issue appear two reports emanating from the department of health of the city of Chicago relative to an epidemic of amebic dysentery, with a focus in a hotel in Chicago. Briefly, the appearance of an unusual number of cases of amebic dysentery about the middle of August aroused the attention of the department of health. These cases were traced to one hotel. Steps were taken immediately to investigate the personnel in that institution, with the result that eventually more than 25 per cent of the food handlers were found to be infested with *Endamoeba histolytica*.

In the meantime it became apparent that many of the guests who had visited this hotel between May and the date of the examinations had become infected and had returned to their homes. There, after a more or less variable period of incubation, they developed the acute symptoms which are typical of this disease. Because of the unusual character of the condition, the diagnosis seems in many instances to have been overlooked. Many of these cases were diagnosed as ulcerative colitis, some appendicitis or peritonitis, and others in other ways. Among those infected were many persons of note, including, for example, some of the leaders of the lumber industry, who had held a convention in the hotel during the end of June, and also many important characters of the stage and of political life. Food handlers, particularly dish washers and kitchen help, are a floating group of workers. Some of those infected had wandered to other hotels, and one neighboring hotel has already shown several cases of infection among food handlers.

Of special interest in connection with the tracing of this epidemic is the fact that two of the food handlers concerned were implicated in a small epidemic that occurred in another Chicago hotel in 1927. At that time seven or eight cases developed, the original case apparently being that of a cook who was thereafter treated in a hospital and pronounced cured. This cook and another food handler also infected in the 1927

epidemic, were found among the employees of the hotel chiefly concerned in the present epidemic.

The situation is apparently unique as far as epidemics of amebic dysentery in this country are concerned. The measures taken by the department of health are outlined in the articles by Drs. Bundesen and Tonney and their associates. One of the most important, so far as the rest of the country is concerned, is the sending of a questionnaire to the 22,000 guests of the hotel during the period from May to November, 1933, with the hope of determining the number of persons infected and now, no doubt, acting as carriers in other parts of the United States. Apparently the condition has already appeared in at least fifty other cities. This indicates the likelihood of its appearance in many more.

From the time when the condition was first ascertained until the first week in November, the health department endeavored to control this condition by the examination of every food handler in the hotel and by the elimination from employment of those found to be infected. In the meantime the hotel continued its regular service in the dining rooms and in its banquet halls. About the first week in November, when the gravity of the situation became more apparent, orders were issued to the hotel to discontinue all banquets, since it is necessary under such circumstances to bring in additional waiters, dish washers and other kitchen help to provide for the excess number of persons eating in the banquet halls and in the dining rooms. Obviously, it is impossible to say just how long these measures will be maintained. A study of the records of persons who stopped in the hotel during September and October will show eventually whether or not the methods followed were efficient for the protection of the public or whether it is necessary, in the presence of such conditions, to discontinue food service entirely.

The assertion has been made that *Endamoeba histolytica* is of uniform virulence, hence some investigators have urged that symbiotic infection with bacteria and *Endamoeba histolytica* is necessary for such serious manifestations as have occurred in connection with the outbreak in one Chicago hotel. Now comes the report of an investigation by Frye and Meloney¹ working in the Department of Preventive Medicine and Public Health of Vanderbilt University, which shows that various strains of amebas may vary in virulence. They studied five strains of *Endamoeba histolytica*, two from a community in the hill country of middle Tennessee, one being a symptomless carrier and the other a chronic case, two additional strains were obtained from acute cases in western Tennessee and the fifth was from another symptomless carrier. The investigators concluded that bacteria or their products or some other substances in the cultures of *Endamoeba histolytica* apparently do sometimes play a part in the production

¹ Frye W. W. and Meloney H. E. Studies of *Endamoeba histolytica* and Other Intestinal Protozoa in Tennessee. VI. The Influence of the Bacterial Flora in Cultures of *E. histolytica* on the Pathogenicity of the Amoebae. *Am. J. Hyg.* 18: 543 (Nov.) 1933.

of lesions in the kitten's intestine—the trial animal in these studies—but that they are not an important factor in the difference in pathogenicity between different strains. This difference is probably due to a difference in the pathogenic activity of the amebas themselves.

The only protection for the public is the detection of every infected food handler and the elimination of such persons from this occupation. Such measures are now being put into effect in Chicago hotels. Once the carriers become ambulatory, however, it is exceedingly difficult to control their movements. Moreover, it becomes necessary for the hotel that wishes to protect itself to insist on an examination of every new person applying for work in its kitchens and dining rooms. As the guests are transients, it is difficult to trace the appearance of the secondary cases. This is particularly true because of the varying incubation period of amebic dysentery, namely, from nine to ninety-four days.

In presenting this material, *THE JOURNAL* emphasizes the subject in order that physicians throughout the country may inform themselves concerning the early symptoms and the methods of diagnosing amebic dysentery. The special articles indicate the necessity for laboratory study to confirm the diagnosis. Efforts should be made to trace to the original focus as far as possible the history of such cases as present themselves. Finally, the public should be made aware of the necessity for more stringent control of food handlers. Repeatedly, American investigators and clinicians have emphasized the increasing menace of amebiasis in this country. Formerly this was considered a tropical disease. Today cases appear in every state. The widespread character of the hazard, particularly in view of the tremendous dissemination that has taken place from the Chicago epidemic, demands the consideration of every public health authority.

AN EVALUATION OF PSYCHOANALYSIS

The article of Leo Kessel and Harold Thomas Hyman¹ on "The Value of Psychoanalysis as a Therapeutic Procedure" represents a rare—and in American medical literature—perhaps even a unique occurrence. It is an objective and an entirely unemotional report of therapeutic results in thirty-three cases treated by accredited psychoanalysts in New York. Its merit lies particularly in the fact that it lacks any preconceived tendency to discredit this new approach to psychogenic disturbances. The authors subject the psychoanalytic results to the unbiased critical scrutiny they would use in evaluating any other form of therapy. In 1930 the Berlin Psychoanalytic Institute published a careful statistical evaluation of 721 cases that had been treated in the period of ten years by its staff, all the members of which are psychoanalysts accredited by the International Psychoanalytic Association. This statistical

report, however, was prepared by psychoanalysts. Perhaps a parallel to Kessel and Hyman's fair attempt at evaluation of the work of psychoanalysts is the report published four years ago by the commission of the British Medical Association. This commission was entrusted with the difficult task of evaluating psychoanalysis as a medical theory and procedure. Its report, however, though entirely objective in tone and attitude, was not based on statistical analysis of cases treated by psychoanalysis.

The attempt of Kessel and Hyman to arrive at objective conclusions regarding the therapeutic value of psychoanalysis is in itself so significant that possible disagreements regarding smaller details of their statistical analysis seem unimportant. Final conclusions can hardly be drawn from a study of such a small number of cases. This is especially true because their study includes cases of such diverse nature as schizophrenia and mild behavior problems. The majority of psychoanalysts at present seem to consider the concepts of psychoanalysis most helpful for understanding the meaning and structure of schizophrenia but feel at the same time that an adequate therapeutic technique for such cases has not yet been developed. The application of psychoanalysis to schizophrenia is still definitely in an experimental stage.

Naturally, many psychoanalysts will question the soundness of some of the principles followed by the authors in the evaluation of therapeutic results. Kessel and Hyman consider it an evidence of failure of the analysis if the analysis ends with a change in the life situation (marital status) of the patient which is contrary to the purpose with which the patient started his analysis, even though the symptoms and the neurosis may have been cured as a result of the treatment. The objection of psychoanalysts would be that frequently the patient's life situation, as, for example, his marriage, has been itself the result of his neurosis. Neurotics, it is said, often choose unsuitable marital partners just as they choose unsuitable vocations, as a result of certain neurotic trends. In such cases it is quite unavoidable that the patient's cure sometimes results in his reorienting himself in his life situation. Leading psychoanalysts claim that improvement of a marital relation is a more frequent outcome of analysis than is divorce. In any case the neurotic patient's expectations and demands at the beginning of the cure are frequently integral parts of his neurosis. It is at present a recognized principle in psychoanalytic practice, as in therapeutic science generally, that, in accepting a patient for treatment, the analyst or physician should not allow the patient to prescribe the conditions for his cure. Just as an internist could not possibly allow a diabetic patient to demand that he be made capable of tolerating a diet of the patient's own choice, so also is it not permissible for a psychoanalyst to undertake the task of making a violin virtuoso out of a person without musical talent.

¹ Kessel, Leo, and Hyman, H. T. "The Value of Psychoanalysis as a Therapeutic Procedure," this issue, p. 1612.

There is no question that both psychoanalysts and other physicians will welcome statistical studies, such as Kessel and Hyman's, which alone can form the basis for sound conclusions regarding the therapeutic efficiency of psychoanalysis. Psychoanalysts, however, will probably feel that the significance of psychoanalysis lies not only in its therapeutic value but perhaps even more in its method of scientific approach and in the theoretical concepts which it contributes to the better understanding of psychopathologic phenomena. They maintain that the soundness of their concepts and methods of studying mental phenomena should warrant the hope of further improvements in therapeutic technique.

COLD ALLERGY AND DROWNING

In so-called predisposed or sensitive persons, light, heat or cold may cause not only cutaneous reactions from contact but also more or less serious internal reactions. It is customary nowadays to speak of such reactions as manifestations of physical allergy, that is, a changed reactivity to physical agents.¹ There are persons who are sensitive to cold in a peculiar manner. In such cold-sensitive persons exposure to cold atmosphere, cold objects or cold water may cause redness, itching, urticarial eruptions, edema of the skin, pain in the joints, sneezing and swelling of the nasal mucous membrane, and asthmatic symptoms. There may develop headache, dizziness, dyspnea, nausea, palpitation, hemoglobinuria and other serious disturbances of a general nature. In cold-sensitive persons, exposure of large areas of the body to cold as, for instance, by bathing in cold water or by walking in a cold, moist wind, may give rise to severe "shock" in which shifting of blood from the external surfaces to the visceral capillaries may be an important factor. It seems also that cold may act to set free a substance or substances that cause severe local and even dangerous general reactions. It is reported that the serum from a part where active reactions to cold are going on may set up such reactions elsewhere. It is reported also that by frequent short exposures to cold the sensitiveness may be reduced ('desensitization'). There is, or at least there seems to be, a close analogy between cold allergy and serum disease.

Apparently, cold allergy may play a special part in serious developments, leading even to death while bathing in cold water. Every now and then instances of death in water occur that are difficult to explain on the score of typical drowning. Probably deaths of this nature may occur in persons who are subject to cold allergy. Obviously even the milder effects of cold allergy may increase the danger to the victim from drowning in the usual sense. Thannhauser² reports that an athletic physician, aged 46 who was subject to

urticaria and other unpleasant effects from contact with cold water, while bathing in a mountain lake developed erythema, itching, and oppression in the chest, he left the water immediately but remained in a state of extreme weakness with strong colonic peristalsis for one hour. In such a case drowning might result from the weakness. Grassl,³ himself the victim of a severe cold allergy with unconsciousness while swimming in cold water on a hot day, mentions the rescue by a bystander of a healthy woman, aged 50, who became suddenly ill with vertigo and vomiting while bathing, the legs swelled up greatly and became very painful. Zum Busch⁴ describes his own case. Since childhood he has been sensitive to cold, on putting his foot out of the warm bed he experiences sneezing and running of the nose, in cold water his hands swell up and become red and itchy, several times when swimming sudden weakness has come on, so that he could reach shore only by supreme effort, followed by collapse and an eruption of giant urticaria about the joints, a similar reaction developed once in a cold air bath. He makes the interesting remark that hypersensitiveness like his may be present only at times.

Two important practical lessons emerge from this consideration. Persons who are sensitive to cold risk their lives bathing in cold water. Also in efforts to determine the exact mode of death in water, the possibility of death from the direct or indirect effects of cold allergy should not be overlooked.

Current Comment

THE ABSORPTION OF DEXTROSE BY RECTUM

There are times and circumstances in which it is difficult, if not actually impossible, to introduce food and drink into the body in the usual way by mouth. The alternative paths on such occasions call for parenteral infusions or rectal administration. The water requirement can be temporarily met with success by such means. With respect to energy intake when oral feeding is interfered with, the situation is much more complicated. Not many years ago it was assumed that rectal feeding was an available procedure. Various types of fluids, notably milk, were introduced into the rectum in expectation of at least a partial utilization through the lower portions of the large intestine. The outcome was in general disappointing except to the degree to which the patient secured water by the attempts at rectal alimentation. An explanation followed when physiologists began to realize that digestion is a prerequisite to absorption, even for compounds as simple as cane sugar. This meant that only so far as the food materials introduced by rectum were pre-

digested or otherwise suitable for absorption could they be properly utilized. With this understanding, feeding by rectum became reduced to the use of the physiologic carbohydrate dextrose. Even with such a readily absorbed product, the possibility of alimentary decomposition by micro-organisms is not excluded. A review of the literature¹ discloses a marked difference of opinion on the absorption of dextrose by rectum despite the record of experiences since the beginning of this century. Last year Scott and Zweighaft² of New York asserted, on the basis of observation on fifty medical students, that there is no evidence of the absorption of dextrose when it is given in a 10 per cent concentration (40 Gm.). The latest study by Collens and Boas³ of Brooklyn is more heartening. They were not primarily interested to know whether absorption, if it did occur, was equal in rate and degree to that occurring when dextrose was given by the oral route. It was important to determine whether a patient to whom dextrose could not be administered orally and for whom the parenteral route was contraindicated could derive the benefits of dextrose when it was in contact with the large intestine. Their evidence was in favor of absorption. As much as nine tenths of the dextrose administered disappeared in some cases in this way. Collens and Boas contend that although dextrose does not pass through the membrane of the colon as rapidly as through that of the small intestine, a sufficient amount is absorbed to warrant recognition of this method as an acceptable therapeutic procedure.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

- November 21 Growing Pains
- November 23 Nutrition versus Malnutrition

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

- November 25 Infections of the Hand

A M A Broadcasts Over National Broadcasting Chain

Arrangements have been completed with the National Broadcasting Company for a series of health broadcasts by the American Medical Association over two of the networks of that company. The time will be each Monday from 3:15 to 3:30 Eastern standard time (2:15 central standard time). The first broadcast will be made Monday, November 20, by Dr. Morris Fishbein. His subject will be "Amebic Dysentery." Subjects and speakers for subsequent broadcasts will be announced weekly in *THE JOURNAL*.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Society News—At a meeting of the Tri-County Medical Society (Union, Ouachita, Columbia) in Camden, October 5, the speakers were Drs. Willis C. Campbell and William C. Chaney, Memphis, on the fracture problem and the anemias, respectively. The Ashley County Medical Society was addressed at Crossett, September 12, by Drs. Francis W. Caruthers, Little Rock, on fractures, Pat Murphy, Little Rock, epilepsy, and Melville W. Hunter, Monroe, La., nephritis.

In Memory of Dr. Bathurst—The *Journal of the Arkansas Medical Society* for October was designated the "Bathurst Memorial Issue," in honor of the late Dr. William R. Bathurst for many years its editor. It contains resolutions adopted by county medical societies throughout the state, and tributes from various other organizations. Dr. Bathurst died, August 31. In addition to having been secretary of his state medical society, Dr. Bathurst was professor of dermatology at the University of Arkansas School of Medicine.

COLORADO

Society News—At a meeting of the Crowley County Medical Society in Ordway, October 11, Drs. George B. M. Baker, Rocky Ford, spoke on "Pneumonia Treatment and Mortality as Compared with Forty Years Ago," William M. Desmond, "Tonsillitis, Its Cause and Treatment," and Earnest O. McCleary, "Etiology and Treatment of Chorea." Dr. William C. Howell, Colorado Springs, addressed the El Paso County Medical Society, October 11, on hyperinsulinism. Mr. Harvey T. Sethman, executive secretary, state medical association, discussed the regulations for allocation of emergency relief funds for medical care. The Larimer County Medical Society heard Dr. George B. Packard, Jr., Denver, discuss "Surgical Abdominal Emergencies in Children," October 4. In Fort Collins—A recent meeting of the Mesa County Medical Society was addressed by Drs. Guy C. Cary, Grand Junction, and Henry H. Zeigel, Collbran, on malignant conditions of the eye and the uterus, respectively. The San Luis Valley Medical Society was addressed in Alamosa, October 7, by Drs. Robert G. Packard and Osgood S. Philpott, Denver, on "Compression Fractures of the Spine" and "Syphilis," respectively. Dr. John A. Schoonover, Denver, spoke on the mentally deficient child before the Weld County Medical Society in Greeley, October 2. At a meeting of the Pueblo Mental Hygiene Association, Dr. Philip Work, Denver, spoke on "Need of Mental Health and How to Obtain It."

CONNECTICUT

The Harry Burr Ferris Lecture—Bradley M. Patten, Ph.D., associate professor of embryology and histology, Western Reserve University School of Medicine, Cleveland, delivered the first Harry Burr Ferris Lecture in Anatomy at Yale University, October 27. The lecture was entitled "The First Heart Beat and the Beginning of the Circulation of the Blood of the Embryo—Studies with Micro-Moving Pictures," and was the first to commemorate forty-two successive years of teaching of anatomy by Dr. Ferris at Yale.

One Hundred and Fiftieth Anniversary of Society—The New Haven County Medical Association will celebrate the one hundred and fiftieth anniversary of its founding January 5. A historical meeting in the afternoon will be addressed by Dr. Creighton Barker, secretary of the society, on "The Founding of the Association in 1784," Dr. George Blumer, "The First Medical Transactions, 1788," Harold S. Burr, Ph.D., "The Founding of the Medical Institute of Yale College," and Dr. Thomas H. Russell, Jr., "Chronicle of Events in the Association after 1840." There will be a display of New Haven County medical bibliography in the Sterling Memorial Library under the direction of Andrew Keogh, librarian of the Yale University Library, and an exhibition of medical memorabilia at the New Haven Colony Historical Association and of medical portraits in the gallery of the School of Fine Arts. A five o'clock tea will be served at the

meeting of the New Haven Colony Historical Association. In the evening, Dr Harvey Cushing will give an address in the auditorium of the Sterling Law Building.

DISTRICT OF COLUMBIA

Health at Washington—Telegraphic reports to the U S Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended November 4, indicate that the highest mortality rate (197) appeared for Washington, and the rate for the group of cities as a whole, 111. The mortality rate for Washington for the corresponding period last year was 158, and for the group of cities, 103. The annual rate for eighty-five cities for the forty-four weeks of 1933 was 108, as compared with 11 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly rates, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

GEORGIA

Society News—The Georgia Urological Society was addressed, October 26, by Drs Louis M Orr, Jr, Orlando Fla, on "A Clinical Consideration of Movable Kidney", Stephen T Brown, Atlanta, "Nephropotosis" James J Ravenel, Charleston, S C, "Congenital Hydronephrosis" Harry Y Righton, Savannah, "Chronic Prostatitis," and Montague L Boyd, Atlanta, "Urinary Tract Infections."—At a meeting of the Tri-County Medical Society (Calhoun, Early and Miller), Dr Daniel L Seckinger among others, spoke on "Treatment of Malaria, with Special Reference to Atebrin."—Philip P Jacobs, Ph D, New York, reviewed the treatment of tuberculosis from the eighteenth century to the present day before the Georgia Medical Society, Savannah, October 10.—Dr Newdigate M Owensby, Atlanta, presented a paper before the Fulton County Medical Society November 2, on "The Mind as a Factor in Bodily Disorders."

IDAHO

Report of Survey of Public Health Administration—The erection of a state health department with suggestions for its organization on a nonpolitical basis was the chief recommendation of Dr Frederick T Foard Jr acting assistant surgeon, U S Public Health Service, in his report on a survey of public health administration recently completed in Idaho. As an alternative, in case the establishment of a state department of health should be considered not feasible at this time, the health official suggested a bureau of public health, so that the organized health work of the state could be maintained separately from the activities of the department of public welfare, which now regulates all matters relating to public health. Further recommendations governed the administration of local health activities, with stress placed on the establishment of full time county or district health units. Twin Falls County has the only county health department in the state on a full time basis. The report urges that the state department of public welfare make an effort to stimulate the reporting of notifiable diseases. The report revealed that while Idaho has a law requiring the examination of food handlers, this requirement is largely neglected. More frequent inspections of food establishments are recommended, with the suggestion that these inspections be conducted by local authorities, under regulations promulgated by the state board of health. Raw and pasteurized milk supplies in Idaho are without adequate sanitary supervision, it was stated, while apparently there is no program for the control and supervision of market milk supplies and no attempt made to stimulate the production of safe milk on a statewide basis. It was recommended that this supervision of dairies and dairy products be placed under the division of sanitary engineering. The dissemination of health information in the newspapers by the department of public welfare was urged. The state department of public welfare has at present no program for education or publicity. There is no state public health association, and annual conferences of state and local health workers are not held. State health laws are badly in need of revision, some are obsolete while others cannot be enforced by the limited personnel of the department of public welfare. Idaho had a state board of health from 1907 to 1919, when the cabinet form of government was adopted and public health work was transferred to the department of public welfare. Although the death rate in the state is low in comparison with the average for the registration area, it has shown a consistently upward trend during the past ten years, having risen from 9.08 in 1922 to 9.99 in 1931. The peak of this period was reached in 1930 with a rate of 10.06.

ILLINOIS

Society News—Dr Frank Garm Norbury, Jacksonville discussed psychoneuroses not requiring institutional care before the Adams County Medical Society, November 13, in Quincy.—Dr Solomon Strouse, Chicago, discussed obesity before the Will-Grundy County Medical Society, November 8.—At a meeting of the Bureau County Medical Society in Spring Valley, November 7, Dr Charles Morgan McKenna, Chicago spoke on 'Diagnosis and Treatment of Diseases of the Kidney'.—Speakers before the Southern Illinois Medical Association November 2-3 at Centralia included Drs Llewellyn Sale and Vilray P Blair, St Louis, on blood dyscrasias and correction of face injuries, respectively, Walter C Alvarez, Rochester, Minn, common causes of nervous indigestion, and Harry S Crossen, St Louis, inflammatory conditions of the female pelvis.—At a meeting of the Iowa and Illinois Central District Medical Association in Moline, October 26, Dr Bert I Beverly, Chicago, spoke on 'Behavior Disturbances in Childhood'.

Chicago

Research in Sex—The National Research Council, Washington, D C, has given \$21,000 to the University of Chicago for research in problems of sex. The amount will be divided into \$8,000 for the investigation of the biochemistry of sex hormones, under the direction of Fred C Koch Ph D, and \$13,000 for investigations in the biology of sex under the direction of Dean Frank R Lillie, Ph D.

Society News—The Chicago Council of Medical Women was addressed, November 3, by Drs Minnie S O Perlstein and Esther T Frankel on 'Lymphogranuloma Inguinale' and 'Use of Ultraviolet Light in Neuralgic Pain,' respectively.—Speakers before the Chicago Surgical Society, November 3 included Dr Fred W Rankin, Lexington Ky, on 'Cancer of the Colon Notes on Its Surgical Treatment'.—At a meeting of the Chicago Pathological Society, November 13, the speakers included Dr Victor Levine on 'Myocardial Changes in Essential Hypertension'.—The theme of the meeting of the Chicago Academy of Criminology, November 9, was classification of prisoners and individualization in management; the speakers were Dr Paul L Schroeder, Andrew Brown, Ph D, and Mr Donald Clemmer.—Dr Arturo Castiglioni, professor of the history of medicine, University of Padua, lectured in the Italian Pavilion, Century of Progress, November 6, his subject was 'The Renaissance of Medicine in Italy'.

INDIANA

Personal—Dr Amos C Michael has been appointed instructor in pathology at Indiana University School of Medicine, Indianapolis.—Dr Thomas J Clutter, Mentone, has been appointed health officer of Kosciusko County succeeding the late Dr Pierre G Fernier Leesburg.—Dr George C Porter, Linton, has been appointed coroner of Greene County.

Society News—A symposium on gastro intestinal disorders was presented before the Indianapolis Medical Society, November 14, by Drs Edgar F Kiser, Richard W S Owen and John A MacDonald. Dr Kiser discussed the Beaumont centenary. Dr Albert Graeme Mitchell, Cincinnati, will speak before the society, November 21, on tonsillectomy, and Drs Harry K Langdon and Okla W Sicks will present a symposium on vaccine therapy and bacteriophage, November 28.—Dr Walter C Alvarez Rochester, Minn, spoke on functional indigestion before the Lake County Medical Society in Hammond, November 3. Dr William D Weis, Hammond was recently elected to life membership in the society, the third member to be so honored in the history of the society.—At a meeting of the Thirteenth District Medical Association in South Bend November 1, Dr William A Evans, Chicago, read a paper on the effect of the depression on health.—Dr Max M Peet, Ann Arbor, discussed "Surgery of the Sympathetic Nervous System" before the Northwestern Indiana Academy of Medicine at Kendallville October 26.

IOWA

Society News—At a meeting of the Woodbury County Medical Society in Sioux City, October 24, Dr Arthur E Hertzler, Halstead, Kan, gave an illustrated talk on diseases of the mammary gland.—Dr John I Marker, Davenport, was elected president of the Southeastern Iowa Medical Society, October 19, at its annual meeting. The principal speaker was Dr Edwin F Schneiders, Madison, Wis, on gynecologic and obstetric emergencies.

Dinner to Dr Taylor—The Wapello County Medical Society was host to the Ninth Councilor District Medical Society and other invited guests at a dinner in Ottumwa,

October 17 in honor of Dr Charles B Taylor, Ottumwa, president of the Iowa State Medical Society. Dr Oliver J Fay, Des Moines, was toastmaster. Speakers included Drs Fred M Smith, Iowa City, on "Dr Taylor as a Man", Daniel J Glomset, Des Moines, "The Future of Medicine in Iowa", John H Peck, Des Moines, "Activities of the State Medical Society," and William C Newell, Ottumwa "Dr Taylor's Local Medical Society Activities." Dr Royal F French, Marshalltown, gave an illustrated address following the banquet on his medical experiences in Indiana.

LOUISIANA

Society News—At a meeting of the Orleans Parish Medical Society, October 9 the speakers were Drs Clyde Brooks on arthritis, Herbert R Unsworth the dangers of the promiscuous use of spinal analgesia, and Thomas B Sellers, infection in the "innocent-looking cervix" as a causative factor in pelvic lymphangitis. Speakers before the Madison, East Carroll and West Carroll Tri-Parish Medical Society in Oak Grove, September 5, were Drs Augustus Street, Vicksburg, Miss, on bone tumors, Berry C Abernathy, Sondheim, treatment of gonorrhea in the male and Leon S Lippincott, Vicksburg, encephalitis. At a meeting of the Eighth District Medical Society in Alexandria, October 4, Drs Guy A Caldwell, Shreveport, spoke on Perthes' disease, John A Lanford, New Orleans, malignant conditions of the breast, Joseph E Heard, Shreveport, toxic thyroid, James M Bamber, New Orleans, diagnosis and treatment of hypertensive and arteriosclerotic heart diseases, and E W Alton Ochsner, New Orleans, carcinoma of the stomach. Dr Lucian H Landry, New Orleans presented a paper on head injuries before the Second District Medical Society September 21, in LaPlace, and Dr Charles J Bloom, New Orleans, discussed brain injuries of the new-born.

MAINE

Society News—Dr Warren E Kershner, Bath, spoke before the Androscoggin County Medical Society, September 28, on "Socialization of Medicine." At a meeting of the Portland Medical Club October 3, Dr Edward A Greco spoke on "Significance of Childhood Type of Tuberculosis." The Oxford County Medical Association was addressed in Bethel September 12, by Drs Joseph H Pratt, Boston, Lester Adams Greenwood Mountain and George E Young, Skowhegan, on "Prevention and Cure of Tuberculosis in Oxford County."

MARYLAND

Old Medal Presented to Museum—A gold medal given to Dr Nathaniel G Keirle in 1866 by the trustees of the Baltimore City Almshouse for extra duty and faithful services rendered during the prevalence of typhus fever in the institution" was presented to the museum of the Baltimore City Medical Society, recently, by the Research Club of the College of Physicians and Surgeons. Dr Keirle was for many years a member of the faculty of the college.

Dr Williams Appointed Professor of Public Health—Dr Huntington Williams, commissioner of health of Baltimore, has been appointed professor of hygiene and public health at the University of Maryland Medical School. Dr Williams has been health commissioner since the death of Dr C Hampson Jones in 1932. The previous year he resigned as secretary of the New York State Department of Health Albany, to become director of health of Baltimore a new position created to increase the efficiency of the city health department (THE JOURNAL, Sept 10, 1932 p 923).

Society News—Dr Chevalier Jackson, Philadelphia, spoke before the Baltimore City Medical Society, November 3, on "Clinical Observations on Suppurative Diseases of the Lung." At a meeting of the Osler Historical Society in Baltimore November 21 the speakers will be Drs Julius Friedenwald and Samuel Morrison on "The Importance of Beaumont's Contribution to Gastro-Enterology," and David I Macht "Mandrites in the Bible Classics Shakespeare and Pharmacology." Dr George W McCoy, director, National Institute of Health Washington D C discussed the St Louis epidemic of encephalitis recently before the Prince Georges County Medical Society at Landover.

Personal—Dr Humphrey Warren Buckler has been temporarily appointed assistant commissioner of health of Baltimore succeeding the late Dr John Frederick Hempel pending a promotion examination to be limited to medical employees of the city health department. Dr Buckler is director of health work in the public and parochial schools and has been con-

nected with the city health department since 1907.—Dr Robert Marshall Allan, professor of obstetrics and gynecology, University of Melbourne, Australia, is in Baltimore observing the work at Johns Hopkins Hospital and the University Hospital.—Dickinson College, Carlisle Pa conferred the honorary degree of doctor of science on Dr James H Mason Knox, Jr, Baltimore, recently.

MASSACHUSETTS

Dr Richards Honored—Dr George L Richards, Fall River, was honored at a dinner, September 27, by the staff of the Union Hospital and the Fall River Medical Society, in recognition of his completion of fifty years in the practice of medicine. A silver platter was presented to Dr Richards on behalf of the hospital staff. Dr Eugene A McCarthy was toastmaster.

Society News—At a meeting of the Norfolk District Medical Society, October 31, Dr Harry J Inglis Boston, discussed paranasal sinus disease and the general practitioner.—The Boston Medical History Club will hear Norman E Himes, PhD, of Colgate University, Hamilton N Y, review the medical history of contraception, December 17.—At a meeting of the Massachusetts Society for Mental Hygiene in Boston, November 23, Dr Lawrence K Lunt Concord, will speak on "The Problem of the Psychoneuroses," and Payson Smith, state commissioner of education, "Teaching Teachers Mental Hygiene."

Courses on Intelligent Living—A course on intelligent living and one on the adjustments of normal youth opened in Boston, November 9 and October 9, respectively, under the auspices of the division of university extension of the state department of education and the Massachusetts Society for Mental Hygiene. Lecturers in the course on intelligent living include the following physicians:

Henry B Elkind Society and Mind
Joseph Pratt The Body and the Mind
Clarence M Hincks New York Mental Health
Clarence A Bonner Danvers Habit Patterns
Karl W Bowman How Man Escapes
Abraham Myerson Fears
Austin Fox Riggs Stockbridge Intelligent Living
Martin W Peck Psychotherapy

Dr Douglas A Thom gave the first four lectures on adjustments of normal youth, and other speakers in this series include Drs Henry B Elkind and Samuel W Hartwell, Worcester.

MISSOURI

Neuropsychiatric Meeting—The Missouri-Kansas Neuropsychiatric Society held its annual meeting in Kansas City October 6, with the following physicians taking part in the program:

Lyle L Woodfin Osawatomie Kan Insanity in Kansas
Raymond C Engley Fulton Mo Prevention of Insanity
Ned R Smith Tulsa Okla Mental Disease A Challenging Problem for Medicine
George W Forman St Joseph Psychosis Accompanying Nephrosis
Howard C Curtis, Wichita Mental Conditions Following Brain Injuries
Thomas L Foster Larned Kan Experience with Diathermy Treatment of Dementia Paralytica Over a Period of Two Years
John M Dunsmore St Joseph Diagnosis in Neuropsychiatry
Daniel V Conwell Halstead Kan Possible Neuro-Endocrine Factor in Intermittent Claudication and Thrombo-Angiitis Obliterans
Myron S Gregory Oklahoma City Paranoia and Paranoid Thinking
Malcolm A Bliss St Louis Nutrition as a Factor in the Social Recovery of State Hospital Patients
Tom B Throckmorton Des Moines The Role of Observation in Neurologic Diagnosis
Ernest Sachs St Louis The Mental Changes That May Occur in Cases of Brain Tumor
Gustave W Dishong Omaha The Significance of Nervousness in Childhood
Guy F Wut Dallas Texas Subconscious Defense Reactions and Their Relation to Organic Disease
Sidney I Schwab St Louis The Use of the Freudian Concepts of the Neuroses by the Neurologist and Internist
Andrew H Woods Iowa City The Contribution of Medical Science to Law

In addition to these papers there was a symposium on encephalitis presented by Drs Elmer T McLaughlin, Jefferson City, Frank Garm Norburn, Jacksonville Ill, George Alexander Young, Omaha, and Edward C Rosenow, Rochester, Minn.

New County Societies—During recent months the Lincoln County and Dallas-Hickory-Polk County medical societies have been organized in Missouri. There were twelve charter members for the former and sixteen for the latter. Officers for Lincoln County are Drs William P Smith Troy, president, Harold S Harris Troy vice president and Joseph J Allevato, Winfield secretary. The speaker for the November meeting

was Dr Charles H Neilson, St Louis, on pneumonia The Dallas-Hickory-Polk society named Dr Albert S Johnston, Wheatland, president, and Dr Joseph L Johnston, Wheatland, secretary After having been inactive for several years, the Perry County Medical Society was reorganized in Perryville, October 11, with Drs Oscar A Carron, Perryville, president, Wade H Abernathy, Menfro, vice president, and Jerome J Bredall, Perryville, secretary

NEBRASKA

District Clinical Assembly—The eleventh and twelfth councilor districts of the Nebraska State Medical Society held a joint clinical assembly at North Platte, November 6-7 Drs Adolph Sachs and Benjamin C Russum, Omaha, conducted a heart clinic and Dr Karl S J Hohlen, Lincoln, presented a film showing methods of diagnosing intracranial injuries Speakers were Drs Albert L Cooper, Scottsbluff, on "Sexual Neuroses as Problems in General Practice", Arthur L Miller, Kimball, "Medical Economics", A D Dunn and William P Wherry, Omaha, "The Problem of Sinusitis", Roy W Fouts, Omaha, "Fractures of the Femur", Floyd S Clarke, Omaha, "Modern Practical Infant Feeding", and John deJ Pemberton, Rochester, Minn, "Goiter", and Boyd Gardner, DDS, Rochester, Minn, "Interdependence of Medicine and Dentistry"

NEW YORK

Society News—Drs John H Gutmann and Albert Vander Veer 2d addressed the Medical Society of the County of Albany, November 15, in Albany, on 'Mortality Statistics in Acute Appendicitis' and 'Rupture of Abdominal Aneurysms,' respectively—Drs John M Swan, Rochester, and James I McKenna, Troy, among others, addressed the Medical Society of the County of Washington, Hudson Falls, October 5, on "Early Diagnosis of Cancer" and "The Mind, Its Origin Growth and Decay," respectively—Drs John A Spengler, Geneva, and Ross L Herold, Willard, addressed the Seneca County Medical Society, October 19, on "Eye Fundus Changes in Systemic Disease" and "Chronic Encephalitis Lethargica," respectively—Dr William J Hoffman, New York addressed the Schoharie County Medical Society, Cobleskill, October 10, on early diagnosis of cancer—Dr Nathan B Van Etten, New York, will address the Westchester County Medical Society at its annual meeting in White Plains, November 21, on "An Economic Prospect for the Physician"—Drs Herman G Weiskotten, Edward C Reifstein and William A Groat presented papers on pernicious anemia at a meeting of the Syracuse Academy of Medicine October 17

New York City

Sir Robert Jones Lecture—Dr Melvin S Henderson Rochester, Minn will deliver the fourth Sir Robert Jones Lecture at the Hospital for Joint Diseases, November 23, on "Surgical Conditions of the Knee Joint"

Medical Program Before Electrical Society—Members of the New York Electrical Society were guests of Columbia University Medical Center, November 15, with the following staff members as speakers on a program, which followed inspection of the buildings

Dr Frederick Tilney Medical Problems in Delinquency
Samuel R Detweiler Ph D Modern Experimental Methods of Studying Development and Growth
Dr Frederick B Plinn Radium Poisoning
Dr Theodore F Zucker Vitamin D Milk
Dr Edward L Howes Strength Measurements of the Healing Wound

Joint Pediatric Meeting—The Philadelphia Pediatric Society, the New England Pediatric Society and the pediatric section of the New York Academy of Medicine met jointly at the academy, October 21 The program included the following speakers

Dr Eugene F Du Bois and James D Hardy, Ph D Heat Loss by Vaporization and Radiation
Dr William H Park A Consideration of the New Preparation of Diphtheria Toxoid
Dr Alfred F Hess New York A Clinical Investigation of the Development of Caries in the Deciduous and Permanent Teeth
Drs Leonard T Davidson and Katharine K Merritt Prophylaxis of Rickets with Viosterol in the Premature Infant A Study of the Clinical Chemical and Roentgenologic Findings
Dr Ade T Milhorat Creatine Metabolism in Muscular Disease
Dr Anna S Topper, Basal Metabolism in Children with Splenomegaly

Dr Park's Retirement Deferred—Dr William H Park, director of the Bureau of Laboratories of the New York City Department of Health, who will reach the age for retirement from the city service, December 30, will be retained at his post for two years the New York *Herald Tribune* reports According to the municipal pension system city employees who reach the age limit of 70 years but who are physically

able and competent to continue their work may apply to the board of estimate for a two year continuance and these requests may be renewed until the applicant reaches the age of 80 Few such applications have been granted recently and those only for six months, it was said A petition circulated to retain Dr Park, who has been in the department for forty years, called attention to his pioneer work on diphtheria and his present research on poliomyelitis, tuberculosis and cerebrospinal meningitis Dr Park also directs the preparation of antitoxins, serums and vaccines, and supervises laboratories for diagnostic tests and analysis of milk, water and shell fish

NORTH CAROLINA

District Meeting—The Fifth District Medical Society of the State of North Carolina held a meeting at State Sanatorium, October 26, with the following speakers Drs James K. Hall, Richmond, Va, "A Consideration of the Individual and the Environment", James D Highsmith, Fayetteville, "Common Bile Duct Obstructions", William B Dewar, Raleigh "Anemia," and Oren Moore, Charlotte, "New Procedures in Gynecology and Obstetrics"

OHIO

Graduate Course on Endocrinology—Allan Winter Rowe, Ph D, Boston will conduct the eleventh graduate course of the Academy of Medicine of Toledo and Lucas County in Toledo, November 22-24, on endocrine disorders Dr Rowe will discuss differential diagnosis of endocrine disorders, non endocrine disorders simulating endocrinopathies, association of endocrine disorders with problems of human fertility and with problems of behavior and personality, and the individual endocrine glands

Society News—Dr George R. Minot, Boston, addressed the Cleveland Academy of Medicine, November 17, on "Anemia—Etiology and Treatment"—Dr Charles A Doan Columbus, was the guest speaker at a meeting of the Summit County Medical Society, Akron, November 7, on "The Role of the White Cell in Disease"—Drs Robert E Cumming and Hans A Jarre, Detroit, were speakers at the meeting of the Academy of Medicine of Toledo and Lucas County, November 3, on "Urinary Tract Infections," with demonstration of serial pyelography The annual joint meeting of the society with the Toledo Dental Society was held November 10 speakers were Dr John W Kemper and Chalmers J Lyons, DDS, Ann Arbor on "Oral Conditions of Interest to Both Professions" and "Cleft Palate and Harelip," respectively—Dr Oscar P Klotz, Findlay, addressed the Auglaize County Medical Society, St Marys, October 12, on thrombo-angitis obliterans—Dr Wilbur C Davison Durham N C, addressed the Mahoning County Medical Society, Youngstown, October 26, on intestinal diseases of childhood—Dr Plinn F Morse, Detroit will address the Cincinnati Academy of Medicine, November 20, on "The Parathyroid Gland"—A symposium on radiation therapy was presented at the meeting of the Montgomery County Medical Society, Dayton November 3, by Drs Harry W Burnett, Henry Snow, Jr, Rudolph J Price, Thomas C Sheridan and Harold H Wagner

OREGON

State Medical Election—Dr Albert M Webster, Portland, was named president-elect of the Oregon State Medical Society at the annual meeting November 4 Dr William T Johnson, Corvallis, was installed as president and Dr Lendon Howard Smith, Portland, was elected secretary

PENNSYLVANIA

Society News—Dr Charles L Scudder, Boston, conducted an all day program on fractures for the Erie County Medical Society, Erie, October 9—Drs Maud L Menten, Pittsburgh and Harold H Finlay, Wilkensburg, and Charles G King Ph D, Pittsburgh, presented a report of "Studies on Susceptibility to and Immunization Against Scarlet Fever" before the Allegheny County Medical Society, Pittsburgh, October 17, and Dr Raymond A D Gillis, Pittsburgh, presented a paper on "Mechanism of Breech Delivery"—Dr David H Boyd Pittsburgh among others, addressed the Pittsburgh Pediatric Society, October 20 on "Treatment of Nephrosis by Intravenous Injection of Acacia"

Philadelphia

Appendicitis Mortality Reduced—A campaign for the reduction of mortality from acute appendicitis in Philadelphia begun in 1928 has resulted in a decrease from 5.97 per cent

of the total number of cases reviewed for 1928-1929 to 344 per cent of those reviewed in 1932, according to a report of the fourth survey in the bulletin of the Philadelphia department of public health. Dr John O Bower, who made the survey under the auspices of the department of health, attributes the reduction in part to education of the public to earlier hospitalization, and less frequent administration of laxatives. The campaign emphasized especially the danger of laxatives, with the result that deaths following their use have gradually decreased from 1 in 12 in 1930 to 1 in 20 in 1932.

Society News—Drs Walter Estell Lee and Harold P Totten, among other speakers, addressed the Philadelphia Academy of Surgery, November 6, on primary carcinoma of the bile ducts.—Drs Edward J G Beardsley and Hugo Roesler addressed the Philadelphia Medical Examiners Association, November 6, on "Asymptomatic Cardiac Enlargement" and "X-Ray Interpretation of Cardiac Enlargement" respectively.—Drs Matthew S Ersner and David Myers presented a study of "The Action of Saliva on Blood Coagulation and Wound Healing in Surgery of the Oral Cavity and Throat" before the Philadelphia Laryngological Society November 7.—Drs Allan D Wallis and Charles R Tatnall, among others presented papers before the Pathological Society of Philadelphia, November 9, on "Coronary Occlusion with Aneurysm of Ventricle" and "Association of Renal Tuberculosis and Renal Calculus," respectively.—Drs Temple S Fay and Ross H Thompson addressed the Philadelphia Neurological Society October 27, on "Dehydration" and "Encephalomyelitis Dissemminata Following Ascending Neuritis," respectively.

TENNESSEE

Society News—Drs Thomas L Bowman, Harriman, and John A McCulloch, Maryville, among others, addressed a joint meeting of the McMinn, Monroe, Loudon and Roane county medical societies at Harriman, September 19 on "Bismuth Therapy in Syphilis" and "Arsenical Dermatitis," respectively.—Dr Dan V German, Jr, Franklin addressed the Williamson County Medical Society September 12, on nephritis in children.—Dr Henry L Douglass addressed the Nashville Academy of Medicine, October 17 on "The Effect of Sympathetic Neurectomy on Interstitial Cystitis".—Drs Marvin H Sandorf and Wallace L Poole addressed the Washington County Medical Society Johnson City, October 5, on lymphogranuloma inguinale and early treatment of syphilis respectively.—Drs J H Eugene Rosamond and Arthur F Cooper, Memphis were speakers before the Gibson County Medical Society, Trenton September 25, on infantile paralysis and diseases of the gallbladder, respectively.—Dr Edwin L Ellis Maryville addressed the Blount County Medical Society November 9, on acute infections of childhood.—Drs Willard H Steele and Samuel H Long presented papers on "Non-surgical Management of Acute Sinusitis and Otitis Media," respectively before the Hamilton County Medical Society, Chattanooga, November 2.

VIRGINIA

State Medical Election—Dr Francis H Smith, Abingdon, was chosen president elect of the Medical Society of Virginia at the annual session in Lynchburg October 25. Dr Robley D Bates, Newtown, was installed as president and Miss Agnes V Edwards Richmond renamed secretary. The next meeting will be held in Alexandria.

Society News—The Post-Graduate Medical Society of Southern Virginia and physicians of the fourth councilor district held a joint clinical meeting at Petersburg, October 17. Dr Wilbur M Bowman Petersburg, discussed "Modern Methods of Birth Control." Dr Frank S Johns, Richmond Extra-Uterine Pregnancy and a symposium on heart disease was presented by Drs Douglas G Chapman and John M Bailey Richmond and James L Wood, Jr, University.

WEST VIRGINIA

Personal—Dr Theodore K Oates Martinsburg was elected president of the Hospital Association of West Virginia at the annual meeting at Clarkburg October 3.—Dr John F Offner Fairmont has been appointed superintendent of the Weston State Hospital for the insane succeeding Dr Cecil Denham. The Weston institution has been designated a receiving unit for the four state hospitals for the mentally ill.

New Members of Public Health Council—The following physicians have been appointed to the Public Health Council of West Virginia: Drs Samuel W Price Scarbro, Walter F West Huntington, William C D McCuskey, Wheeling, Benjamin H Saint Charleston and Morgan T Morrison

Sutton. Dr Albert H Hoge, Bluefield, was reappointed and W E Minghini DDS, Martinsburg, was also appointed under authority of a law passed by the last legislature adding a dentist to the personnel of the council.

WISCONSIN

Graduate Course in Urology—The Wisconsin Urological Society is sponsoring a graduate course in urology planned especially for the general practitioner. The course began with an all day meeting at the Milwaukee Athletic Club November 10, when Wisconsin physicians discussed various urologic conditions and Dr Vincent J O'Connor, Chicago was the guest speaker, on "Traumatic Lesions of the Urogenital Tract".

Society News—Drs Reginald H Jackson, Madison, and Frederick A Stratton, Milwaukee, addressed the Milwaukee County Medical Society, November 10 on "Sciatic Pain Due to Chronic Sacro-Iliac Sprain" and "Treatment of Bram Injuries" respectively.—Prof Arturo Castiglioni of the University of Padua addressed the Milwaukee Academy of Medicine, November 7, on "The Conception of Infection and Contagion Through the Centuries".

Twenty-Fifth Anniversary Meeting—The Wisconsin Anti-Tuberculosis Association held its twenty-fifth annual meeting in Milwaukee, October 27-28. Among subjects discussed were the need for education in tuberculosis, treatment by surgery and tuberculosis and the child. Speakers included Drs William A O'Brien, Minneapolis, Eben J Carey, Milwaukee, and Robinson Bosworth, Rockford, Ill. At a jubilee dinner Friday evening Dr Mazzyck P Rayenel, Columbia, Mo was the guest speaker. Dr J Gurney Taylor, Madison, was reelected president.

Course on Medical Economics—Mr Theodore Wiprud executive secretary of the Medical Society of Milwaukee County, is presenting a series of lectures on medical economics to senior students at Marquette University School of Medicine Milwaukee. The following subjects will be discussed:

Why Consider Medical Economics?
The Physician Should Adopt Business Methods.
The Physician and His Investments
Medical Charity—Where Should It Stop?
Fair Competition Among Physicians
Contract and Panel Practice
Health Insurance
Organized Medicine Meets Current Problems

Presentation of this course is in line with the recommendations embodied in a resolution adopted by the House of Delegates of the American Medical Association at its session in Milwaukee last June, according to *Milwaukee Medical Times*.

FOREIGN

Harben Lectures—Dr Jack Cecil Drummond professor of biochemistry, University of London, delivered the Harben Lectures at the Royal Institute of Public Health, October 9, 10 and 11. His subjects were recent studies of the chemical nature of the vitamins, physiologic function of the vitamins and vitamins in relation to practical problems of human nutrition.

Study of Criminals in Poland—To determine the best methods for the segregation and individual treatment of prisoners the Commission for Criminal Biological Researches of Poland has introduced a test for criminal biologic investigations, which all prisoners whose sentences do not expire earlier than Jan 1 1935, must undergo. The physical, mental, psychologic and social status of the prisoners will be examined with special emphasis on 'social prognostics'. The objective of the plan is to establish a progressive penitentiary system. Supplementary to it the Ministry of Justice has instituted a course in psychiatry, criminology and anthropology for prison medical attendants.

League of Nations Cooperates with China—Dr L Rajchman director of the Health Organization of the League of Nations Geneva has been sent as a delegate to China for a year to assist the government in coordinating the activities of the league's experts in China and to act as liaison officer for the government and the league. Dr Rajchman's appointment is part of a plan of general cooperation in all technical fields which grew out of an original contact in the field of public health a survey of port health and maritime quarantine conditions made by the league in 1929. The government has asked the aid of the league in its plan of reconstruction by (1) the presence of a permanent liaison officer (2) the aid of experts for particular projects (3) assistance in framing particular projects (4) help in training Chinese technical officers and (5) assistance in finding experts to carry out the reconstruction and to facilitate intercourse between China and other countries.

(From Our Regular Correspondent)

Oct 28 1933

The Need for a New Class of Investigators

Sir Thomas Lewis, a leading cardiologist, is director of the Medical Research Council department of experimental medicine at University College Hospital, an appointment unique in uniting experimental with clinical medicine. No one is better qualified to speak of the importance of this union. In the Harvard oration at the Royal College of Physicians he pointed out that it was exemplified in Harvey, who had been termed the father of physiology, but that it was more, for his child was clinical science, out of which physiology and pathology were afterward born. Since his time knowledge had grown, and where there had been one science many had sprung up. There was need to guard against the obsession of recent years that useful discoveries were purely the prerogative of laboratories. The proper practice of medicine rested on a tripod consisting of studies of the living in health and in disease, studies of the dead, and correlated studies of the lower animals.

A great need today was a group of men primarily clinicians but accustomed by training and daily experience to wrestle with scientific problems, men who, in place of relatively complete knowledge of some laboratory science, had in the first place intimate acquaintance with the relevant diseases as seen in living man who had also acquired sufficient knowledge of related physiology and pathology to enable them to grapple with the problem in detail and in its wider aspects and to drive successfully to a practical goal. Such work was not the type to which those busily engaged in practice could give themselves in leisure hours with success. If this project was to be accomplished, it would be necessary to set free men with aptitude for the work, to form a phalanx of trained clinicians who could bring clinical science to a new pitch of scientific efficiency. Clinical science should lead the medical science of the future as it did in the past.

Exploiting the Deaf

In the annual report of the National Institute for the Deaf attention is called to considerable success achieved in protecting the deaf against the purchase of unsuitable aids to hearing, which are extensively advertised. Increasing numbers of the deaf consult the institute before negotiating for such aids, and a growing number of journals now decline advertisements from firms who are not willing to agree to the conditions for entry on the institute's list of approved firms. These conditions are that the most suitable aid indicated by the conditions of the client, whether electrical or mechanical, will be recommended, and that, if no aid appears likely to help, the client will be informed. Further, in the event of the purchaser's being dissatisfied with the hearing aid, a refund will be made, less a sum for expenses. Benefit societies and other bodies who assist their members to obtain aids to hearing are refusing such help unless the firm dealt with accepts these conditions. The report states that the deaf have been seriously exploited under the guise of sympathy and the pretense of help in circulars from certain firms, who persuade even those who are extremely deaf to purchase their instruments and who refuse any final adjustment even when the instrument proves to be of no service.

The Earliest Remains of Man

What are claimed to be the earliest remains of man have been discovered by the East African archeological expedition and are on view in the British Museum, with specimens of

the associated fauna and of stone tools. At a meeting at the Royal Anthropological Institute, Dr L. S. B. Leakey, leader of the expedition, showed a mandible found at Kanam, which belonged to the beginnings of the Lower Pleistocene or even the Pliocene period. In many characters the type did not differ from primitive *Homo sapiens*, but roentgen examination of the roots of the molar and premolar teeth showed that it should be separated from the species *Homo sapiens* and rank as a new species of the genus *Homo*, for which he proposed the name *Homo kanamensis*. He regarded the new species as a true lower Pleistocene ancestor of *Homo sapiens*. It was at least as old as its distant cousins *Pithecanthropus* from Java, *Smantropus*, from near Peiping and *Goanthropus*, found in England. While these formed genera distinct from the line of modern man, *Homo kanamensis* belonged to his genus and formed the species nearest related to him. He had a pronounced chin, and the arrangement of his teeth, as well as their size agreed with those of *Homo sapiens*.

The expedition also found, at another place in East Africa, Kanjera, ancient human remains but more recent than the Kanam specimen. Skulls were found that were established as belonging to the middle Pleistocene and are held to be the oldest remains of *Homo sapiens* yet discovered. The skulls were larger and thicker than those of modern man and their height was low in relation to the length. They had not the pronounced brow ridges that belong to the types of man dissociated from *Homo sapiens*. They were a generalized and rather primitive example of our own species and an advance over the Kanam man.

The stone implements found were of the highest significance. With the Kanam man were found crude implements, roughly chipped, with the Kanjera man a more highly developed type of the coup de poing, or hand ax. From another East African site, Oldoway, was found previously a series of stratified deposits which showed for the first time an unbroken and continuous series of the evolution of this hand ax culture, into which the stone implements of Kanam and Kanjera fitted. Dr Leakey suggested that East Africa was near the center of the development of this culture, if not the actual center. On the other hand, the forms of man characterized by great brow ridges was associated with the flake culture of stone implements.

Sudden Death of Donald J. Armour

Mr Donald J. Armour, senior surgeon to the National Hospital for Nervous Diseases and consulting surgeon to the West London Hospital, died at the age of 64 while attending a council meeting of the Medical Society of London, of which he was treasurer. He was apparently in his usual health and had given his treasurer's report and sat down. He was taken suddenly ill and died immediately. The meeting was adjourned. A member of a well known Canadian family and the son of the chief justice of Ontario, he was born in 1868 and educated at the University of Toronto. Subsequently he entered the medical school of University College, London, where he became demonstrator of anatomy and attracted the attention of Sir Victor Horsley, the pioneer of neurologic surgery in this country, and assisted him in his operations. He was appointed assistant surgeon to the National Hospital for Nervous Diseases and also surgeon to the West London, Italian and Belgrave hospitals. Though an energetic general surgeon, he made his reputation mainly as a neurologic surgeon, on whom the mantle of Horsley had fallen. He delivered the Arris and Gale lectures at the Royal College of Surgeons on the surgery of the gasserian ganglion and gained the Jacksonian Prize for his essay on morbid growths of the vertebral column and spinal cord, in special reference to their amenity to operation. As Hunterian professor he lectured at the college on the surgery

of the spinal cord and its membranes. He contributed many papers to the medical journals on head injuries, the surgery of the nervous system and abdominal surgery. For the "System of Treatment," edited by Latham and English, he wrote the articles on the surgical diseases of the scalp, the cranium, the meninges, the brain, and the spinal column and cord. During the war he was specialist to numerous military hospitals. He leaves a widow, one son and two daughters.

Increased Tax on Imported Insulin

England has been foolish enough to abandon her system of free trade. This is due to the fact that the dominant political party does not understand economics or, what is nearer the truth, the leaders don't want to understand economics as this would deprive them of their pseudopatriotic protectionist propaganda. The list of taxed commodities is constantly being extended at the request of interested persons. But the request to increase the present 10 per cent tax on imported insulin to 33 per cent has raised an outcry in the *Star*. Why inflict hardship on poor people who are ill? Their insulin supply already often costs \$3 a week. The *Star* publishes a number of letters from physicians protesting against the proposed increase. One states that he has known patients to halve the dose prescribed, because they could not pay for the full one. Another point is that a large number of diabetic patients cannot buy insulin at all, they obtain it by charity or at the expense of the state. Increased cost means depletion of charitable funds, already too small, or increased burdens on already overburdened taxpayers.

Organization of a Center for Convalescent Serums

Since it has been recognized that the serums of convalescents have in some infectious diseases a preventive and curative value, efforts have been made to establish centers where supplies of convalescent serums may be kept on hand for use in case of epidemics. It has not been found easy to organize such a center. In children's hospitals, one can obtain serum from convalescents from measles, pertussis, scarlet fever and bronchopneumonia, although it is dangerous to take too much blood from young patients recovering from such diseases. The small supply thus secured is not sufficient to supply the physicians of the city who require serums for their clientele. A model organization has been perfected, in the children's clinic at Strasbourg by Professor Lowenberg, the details of which he recently announced. There is provided a stock of convalescent serum for measles, scarlet fever and poliomyelitis. In this connection the discovery of the potency of the serum of adults who have been in contact with poliomyelitis patients is important. The serum of many physicians and nurses can be employed after its immunizing value has been demonstrated by inoculation in the monkey. Lowenberg gave an inventory of the serums that his hospital possessed. Of measles serum about a liter was collected last year. Blood was taken from more than thirty patients and there were about twenty requests for serum. The stock of serum of scarlet fever patients reached 3.5 liters. Blood was taken from patients in thirty-five instances in securing this supply, and forty-one requests for serum were met. The stock of serum for poliomyelitis was derived chiefly from adults who had the disease during the epidemic of 1930. Nearly 4810 cc was collected. 515 cc was placed at the disposal of physicians requesting it. Thirty-eight samples of blood were required to produce this amount of serum. Seven requests for serum were satisfied. Lowenberg has not yet been able to collect all the necessary evidence with which to determine the final results in cases treated with serum but,

in all the cases in which a report has been received, the results were regarded as favorable, particularly as regards the scarlet fever serum in a number of grave cases.

Insects from the Near Orient

At a session of the Société de pathologie exotique, Tanon and Neveu announced the discovery of a new species of cockroach previously unknown in Paris. Speed in methods of travel has increased, in late years, the geographic distribution of many insects. Some species that have been restricted heretofore to Asia or Africa are beginning to appear in Europe. Three years ago the hygienic services of the police were compelled to deal with houses invaded by ants from Indo China. More recently a building became infested with ants from Argentina, and a few weeks ago, a house was invaded by cockroaches that were different from any species known in France. The new species is called *Sapella supellectum*, which is found normally in the Mediterranean Orient, and especially in Egypt, Palestine and Syria. An inquiry revealed that the apartment had been inhabited by a Syrian family whose baggage contained cockroaches. The insects found in the radiator coils favorable thermic conditions for their reproduction. They are difficult to get rid of. The use of insect powder with a sodium fluoride or pyrethrum base, and spraying of pyrethrum powder with an electric atomizer do not destroy the insects. The question of the best method of destroying these insects has been considered by several members of the society. Mr. Navelier recommended the use of "rough-on-rats" (arsenic). Mr. Galliard reported that his laboratory of parasitology was invaded by cockroaches. Arsenical salts were found to have a sufficiently destructive action.

The Maggot Treatment of Wounds

The presence of the larvae of flies on wounds was regarded in ancient times as favorable to recovery. The surgeon Larrey, during the Napoleonic campaigns in Syria and Egypt, made such observations, but his remarks were received with incredulity. American investigators have recently developed this method. Professor Brumpt, during a recent visit to the United States, observed the good results secured, which he studied carefully. He plans to introduce this method in France. It is therefore necessary to select the larvae with great care. Mr. Brumpt has established a breeding place in Paris, in the laboratory of natural history, which is under his direction at the Faculté de médecine. In a communication to the Academy of Medicine he described the technique that he employs. The larvae liquefy the organic products, on which they live, by means of proteolytic ferments. Their products of secretion make alkaline the wounds primarily acid, and thus diminish considerably the number of microbes. Sterile extracts of larvae also may produce, in some cases, satisfactory results.

Dedication of the Hôpital de Grange-Blanche

The immense Hôpital de Grange-Blanche, at Lyons, has been, in part, completed. Part of the funds for the building of the hospital were supplied by the Rockefeller Foundation. Mr. Edouard Herriot, who in spite of other important political duties was mayor of Lyons for twenty years seized this opportunity to erect a great hospital. He brought together on one site all the hospital services designed to replace the various old hospitals scattered over the city and at the same time moved to this site the whole Faculté de médecine, which was much cramped in its old quarters in the downtown section. It is therefore a gigantic city of medicine—comprising hospitals and institutions of instruction—that has been erected at the gates of the city of Lyons since the enormous space necessary (17 hectares, or 42 acres) could not be procured in the center of the city. Special means of transportation have been created to connect the new city with the old. The professors and the

students, to tell the truth, complain about the great distance, as they lose much time going back and forth. A large dormitory has been added, but that does not satisfy the many students who live at home, in Lyons, at less expense. The new hospital is composed of separate pavilions each of which constitutes a complete hospital in itself, with a surgical department and two medical departments. There will be twenty-two pavilions, thirteen of which will have the complete equipment of a clinic. The hospital will have a total of 1,544 beds. The science buildings, the laboratories, the maternity, the nurses' training school and the school for visiting nurses for social hygiene, and the administrative departments will occupy special buildings. As a number of pavilions were ready to function and to receive patients, the formal opening of the *Hopital de Grange-Blanche* took place on the national holiday, this year.

BERLIN

Reorganization of the Krankenkassen

In several recent letters, the reorganization of the federal health insurance system of Germany has been considered. Now the federal ministry of labor, which has control of the entire health insurance system, has issued a circular letter to the governments of the German *lander*, from which an idea of further reorganization may be derived. There were a number of unpleasant, if not injurious, practices that needed to be eliminated. In this letter the point is stressed that the selection of personnel, particularly as regards the more important posts, is to be based on objective and not personal points of view. Candidates must be adapted to the work. In the event of friction arising among the personnel, the possibility of transferring or exchanging appointees should be considered. The standing and the compensation of the confidential physician continue to be assured by suitable regulations, likewise his impartiality and independence of action remain protected. The provisions bearing on his status must be strictly observed in order to protect the well established interests of the insurance corporation as a whole. With a view to economy of administration, a merger of *kranken-kassen*, especially of *kranken-kassen* whose headquarters lie in the same insurance zone, is recommended, but, for the present a merger of *kranken-kassen* with entirely different characteristics should be avoided, or a mere administrative merger can be effected. Every measure should be tested as to its feasibility and its economic advisability. The members of the various administrations are individually responsible for the conduct of affairs. The preparation in advance of a sufficiently detailed budget is needed. The goal that must be kept constantly in mind is such an economical administration as to make it possible to lower the insurance premiums paid by individual members of the *kranken-kassen*. The question as to whether it is advisable, under certain conditions, for the *kranken-kassen* to produce and dispense directly various medicines and bandage material, without taking account of the pharmacists, requires special and careful consideration, the decision presupposing the weighing of the interests of the *kranken-kassen* against the interests of the liberal professions. It should be borne in mind that while it is doubtless true that the *kranken-kassen* save considerable money by manufacturing certain items of their needs, the pharmacists feel that their interests are thereby damaged and emphasize that their preservation constitutes an important factor of the public health service. In considering the feasibility of economic measures, the administrations of the *kranken-kassen* must not attach sole importance to present conditions but must show proper appreciation of future conditions and the rightful interests of the insured. Especially with respect to the procuring of radiologic

and other therapeutic apparatus, it should be considered that the development of the service of confidential physicians will naturally entail a wider use of diagnostic agents. A hasty abandonment of such agencies may lead to the wasting of public property, to the damaging of honorable interests and to a marked increase of the burden laid on the insured. It is brought out in this document that the factories owned and managed by the administration of the *kranken-kassen* have their justification, as it is often next to impossible to enter into suitable arrangements with the various occupational groups. When such conditions prevail, the members of the *kranken-kassen* as a whole can hardly be expected to assume unnecessary burdens in favor of minorities.

Effects of Irradiation on Excretion of Sex Hormone

During the course of their studies on sex physiology, Professor Doderlein, gynecologist of Munich, and the pathologist Professor Borst recently discovered a new general effect of irradiation. In the Döderlein Radiologic Institute, all patients with uterine cancer have, since 1913, been subjected solely to combined roentgen and radium treatment. Patients with cancer of the genitalia excrete in the urine, in 81.8 per cent of the cases, the sex hormone of the anterior lobe of the hypophysis. Since implants of cancer tissue never contain this sex hormone, the formation of this substance in cancer patients takes place evidently in the anterior lobe of the hypophysis. It is common knowledge that young women who have undergone ovariectomy (through either a surgical or a radiologic operation) excrete for a short time after the intervention, in the urine the sex hormone of the anterior lobe of the hypophysis. Ovariectomized women and women with genital cancer appear, therefore to act in the same manner with respect to the excretion of the sex hormone of the anterior lobe of the hypophysis. To ascertain the significance of the excretion (following irradiation of cancer) of the sex hormone of the anterior lobe of the hypophysis, Doderlein and Borst selected for their investigations elderly women who had not menstruated for many years. The urine of these women was examined as to the sex hormone content before and after the combined roentgen and radium treatment. The authors ascertained that, in such cases, before the irradiation the sex hormone was excreted in only 63.16 per cent but after the irradiation in 100 per cent of the women. The investigators assumed, therefore, that therapeutic roentgen and radium treatment always exerts a distant influence on the prehypophysis and stimulates it to increased secretion of the sex hormone of the anterior lobe of the hypophysis. This assumption finds confirmation in the observation that men affected with cancer of various organs frequently excrete in the urine, following local radium irradiation, increased quantities of the sex hormone of the prehypophysis.

Traffic Accidents

According to a report of the federal bureau of statistics, 22,835 fatal accidents occurred in Germany in 1931, of which 7,526 were traffic accidents. Owing to improvements in traffic arrangements, recent years have shown a decrease in fatal accidents. An accident of average severity can be assumed to require the expenditure of 4,500 marks, so that the total damage from the financial point of view alone is considerable. As to the causes of accidents, technical errors or weaknesses of vehicles and faulty conditions of the roads play a comparatively small part. The main causes concern the drivers and the pedestrians themselves.

The German Academy of Scientists in Halle

The Kaiserlich Leopoldinisch-Carolinische Deutsche Akademie der Naturforscher has come more to the front through the admission of many new members. The academy was founded in 1652 when four physicians in the Bavarian city of Schwem

furt formed a group with the object of promoting research in the natural sciences. The academy received imperial recognition and was gradually accorded numerous privileges customary in the middle ages but which are now no longer held. It is not a state academy, after the manner of the large academies in various countries. It has a department of mathematics and the natural sciences and a medical department, which departments are divided into a number of special groups. Regular sessions are held once a month. It has its own research fund, which is used for the publication of *Nova Acta Leopoldina* and for the promotion of research. For a number of years, Professor Abderhalden, of the department of physiology of the University of Halle, has served as president. Since 1904 the academy has had its own building, with a library containing about 100,000 volumes.

VIENNA

(From Our Regular Correspondent)

Oct 4 1933

The Ever Widening of Child Welfare

The first report of the activities of the municipal department of child welfare, just published by the public health service of Vienna, contains many items of interest to the medical profession. It describes the work of the welfare department for mothers and infants, and the care of children and young persons who lack normal adjustments. The department of child welfare, created in 1917, comprises fourteen main districts with 234 local centers each of which is in charge of one female senior social worker and a female assistant social worker. In 1931-1932, no fewer than 162,850 families with 260,040 children were visited by these social workers. A children's placement center has been established, which subjects to a medical examination and an educational test all children that come under the care of the city of Vienna and thereupon places them in a hospital or in the care of a private family. In 1931-1932, 7,960 children were so placed. Also the organization and development of the kindergartens were taken over and so to speak, monopolized by the municipality of Vienna. Vienna has control of 349 kindergartens. In many cities the kindergartens are private undertakings. Last year, 19,423 children received full supervision and maintenance in these municipal kindergartens, as against ninety-three kindergartens with 4,700 children in 1913. Only 15 per cent of the children contributed small amounts toward the cost of their meals. Aid in the care of the health of the oncoming generation is given also in the *Kindelhorte* which are designed mainly for children who have no supervision at home during the day. About 20,000 children aged 6-14 years were cared for in this manner during the last fiscal year. Another interesting feature is the "Säuglingsküche-Aktion," which with the aid of the city of Vienna, provides gratis a baby's outfit for all new born children whose mothers are without funds. Last year, 10,708 packages of infants linen were thus distributed. One of the most important departments of the bureau of child welfare is the consultation service for mothers, of which there are thirty-five, in which 248,523 children were examined last year and their mothers advised as to their care. In addition there are two consultation centers for prenatal care which are in charge of gynecologists and are available to every woman. Here is located also the mothers' aid service the chief object of which is the combating of congenital syphilis. There are special rewards for mothers who will nurse their children (40 Austrian shillings per child annually). Another branch of the bureau of child welfare is the free lunch service for school children. In sixty-seven public schools more than 12,000 children received daily a warm substantial meal. Mention should be made also of three further branches of the bureau of child welfare the consultation service on child training the hospital social service and the

outing service. In 1931-1932, the outing service provided 25,000 children with a summer outing of from four to eight weeks.

Recent Regulations for Animal Experimentation

It is not likely that a general renunciation of experiments on living animals will ever be brought about. Remedies can be studied and tested only on living organisms, and the standardization of many therapeutic agents can be effected only by the use of animals. Animal experiments must frequently be used for instruction purposes. However, every serious-minded investigator must be conscious of his accountability for his work on animals, in other words, he must exercise self-discipline. The establishment of regulations pertaining to animal experimentation has been repeatedly attempted and desired by physicians, possibly for the reason that antivaccinationists are inclined to exaggerate and to display ill will. Their crusade against scientific medicine in favor of treatment by so-called natural methods has led, in some countries, to the enactment of laws directed against vivisection. Recently Austria's Society for Prevention of Cruelty to Animals has submitted to the government a plan for legislation, which is not unreasonable. The proposals cover the following points. Only scientific public institutions, and institutes and laboratories that are under state supervision, shall be permitted to do animal experiments. The director of an institution must be held personally responsible for all experiments performed in the institution. Vivisection may be used for instruction purposes only when no other method, as, for example, an instruction film, is available. Operations on animals may be performed only by physicians and veterinarians. With the permission of the director of an institute, and under his responsibility, students who have been pursuing their studies at least three years may be allowed to perform such experiments. During the whole duration of the intervention, the animal must be protected against pain by general or local anesthesia. The same animal may not be used for vivisection more than twice. These criteria do not differ materially from the "principles pertaining to the performance of scientific animal experiments," which the Schweizerische medizinisch-biologische Gesellschaft established a short time ago. In the *Mitteilungen der Wiener Aerzteschammer* for October, 1933, this problem is briefly discussed.

The Annual Meeting of Alpine Physicians

In Baden, near Vienna, the ninth Convention of Alpine Physicians October 2-3, attracted surgeons and internists who practice in the Alpine regions, chiefly, Styria, Tyrol, Salzburg and Austria, but also North Italy, Yugoslavia, Germany and Switzerland. About 400 men and women attended.

DISEASES AND INJURIES OF THE PANCREAS

The first topic on the program was "Diseases and Injuries of the Pancreas." Prof. Dr. Walzel of Graz presented the surgical, Professor Berger of Graz the pathologic, and Dr. Hamperl the internist's side of the question.

THE BANG BACILLUS IN MAN

The second topic was "Infection with the Bang Bacillus in Man." The importance of this disease has been recognized only in recent years. The condition is so common in the Alpine regions that the ministry of public health found it necessary to supply the medical profession with a bulletin containing information on the etiology, the course and the prophylaxis of the disease. Questionnaires have been sent to the local health authorities to secure an insight into the incidence of the disease in Austria. Prof. Dr. Lauda of Vienna discussed the symptoms, treatment and differential diagnosis while Professor Russ discussed the bacteriologic and the serologic aspects. Professor Schnurer of the college of veterinary science in Vienna, presented an account of the infection in animals.

THE PROBLEM OF ABORTION

The third topic was "The Problem of Abortion." Professor Stigelbauer of Wiener-Neustadt gave statistics on abortion in Austria. Professor Weibel of Vienna spoke on therapy, Dr. Hies of Klagenfurt on the technique of artificial abortion, and Professor Zacherl of Innsbruck on the late sequels of abortion. A large number of addresses were delivered on these three main topics. The session closed with social events, excursions and concerts. There was an instructive exhibit of medical and chemical preparations and apparatus.

Sudden Death of Professor Herrschmann

Professor Herrschmann, an eminent court psychiatrist, died suddenly of angina pectoris, aged 44. While serving as assistant physician in the Vienna Psychiatric Clinic, he wrote many interesting articles, among which were "Laws of Marriage in Their Bearing on Mental Patients" and "Accountability." During the codification of the new Austrian penal code, he was summoned as an authority in drafting the chapters on the status of mental patients. Other well known studies are "Chronic Barbitol Poisoning and Syphilitic Psychosis," and a large number of neurologic studies on the minute structure of the brain.

AUSTRALIA

(From Our Regular Correspondent)

Sept. 11, 1933

The Fourth Australian Cancer Conference

The mortality rate from cancer has increased in the past year. For 1931, the deaths from cancer in the commonwealth per hundred thousand of mean population were 105 for males and 97 for females. These rates showed a considerable increase over the previous year. Of the total deaths from all causes in Australia the proportion due to cancer continued to rise and in 1931 one death in every nine in males and one in every eight in females had been caused by cancer, this proportion being the highest yet registered in the commonwealth. The population of Australia during the past fifty years has been changing considerably in composition as regards the age groups. In 1881, only 2.5 per cent of the population lay in the age group of 65 years and over. In 1931, 6.03 per cent of the population lay in this age group. Consequently, a larger number of persons are living into what is known as the cancer age. It was found also that in that age group the cancer mortality rate was rapidly increasing. On the other hand it was found that in the age groups below 65 years, an actual diminution in the cancer mortality rate had become evident in recent years, the rate for 1931 being below that for 1911 and 1921. This diminution in the cancer mortality rate for the age groups under 65 years might be considered a favorable sign and might with justification be attributed at least partly to the efficacy of modern treatment. In elderly persons cancer comes more as a terminal event, cure is less likely to occur and the mortality rate is consequently but little affected by treatment.

The steady rise in the cancer mortality rate appeared mainly in relation to carcinoma of various organs. The mortality rate for sarcoma was at practically the same figure it had been twenty-five years before.

The mortality from cancer of the tongue in males, although the year 1931 showed an increase over the previous year, still remained at a lower level than it had been a decade or two previously. In females, on the contrary, the mortality rate (although cancer of the tongue was relatively rare in females) was higher in 1931 than at any previous time in the past twenty-five years.

Although in cancer of the tongue in males the tendency of recent years had been toward a diminution in the mortality rate, the mortality rate had increased in all other sites of

cancer, with the possible exception of the skin. In respect to some regions, however, the mortality rate was increasing much more rapidly than in others. Thus, in females the mortality rate from cancer of the breast had increased more rapidly than that for cancer of the female genital organs. In 1908 and 1931 the respective rates per hundred thousand of mean population were in the female genital organs, 15.3 and 20.9, an increase of 36 per cent, and of the female breast, 10.2 and 18.6 or 82 per cent increase.

The region in which the most rapid increase in the mortality rate from cancer had occurred was the digestive tract. Here the increase since 1908 had been 146 per cent in males and 120 per cent in females.

The mortality rate per hundred thousand of mean male population in 1908 was 25.2 per cent, in 1930, 49.7, and in 1931, 62.0. For females the rates for the same years were 20.1, 35.9 and 44.3 per cent, respectively. In males in 1931, one death in every 17 deaths from cancer was attributed to cancer of the digestive tract, in females the proportion was one in 22.

In cancer of the skin the mortality rate, which until 1918 rose steadily, had since shown a distinct though fluctuating tendency to fall. In 1908 the rate in males was 3.1 per hundred thousand of mean population. In 1918 it had risen to 5.0 per hundred thousand. In 1930 it had fallen to 4.0 and in 1931 to 3.5 per hundred thousand.

Infant Welfare in Australia and New Zealand

Owing mainly to economic conditions, the downward trend of infant mortality rates for 1932 have been arrested and in a few instances have risen slightly.

The state of affairs can be appreciated from the following table:

Annual Infantile Mortality per Thousand Births

Year	Queensland	New South Wales	Victoria	South Australia	West Australia	Tasmania	New Zealand
1928	25.5	54.9	55.0	47.5	48.1	64.0	38.9
1929	46.1	56.6	47.2	40.9	60.2	63.2	34.1
1930	40.2	49.8	46.6	48.4	46.7	50.6	34.5
1931	36.6	43.5	44.5	36.4	41.5	46.0	32.2
1932	40.2	41.0	43.0	36.7	44.6	40.5	33.7

Below are the rates given in five year periods. New Zealand has the lowest infant mortality rate in the world, followed by Queensland and South Australia.

Average Infantile Mortality in Five-Year Periods

Year	Queensland	New South Wales	Victoria	South Australia	West Australia	Tasmania	New Zealand
1913-1917	63.2	68.3	69.8	68.1	65.7	63.4	51.9
1918-1922	59.5	63.6	65.9	59.0	63.7	64.9	46.8
1923-1927	51.1	57.6	59.1	51.2	51.6	53.5	40.5
1928-1932	41.7	40.2	47.4	42.0	47.4	50.9	34.1

The extension of welfare activities has generally been arrested but an interesting development in New South Wales is an airplane baby clinic for service to mothers in isolated centers. This was inaugurated Oct. 5, 1932. Queensland, New South Wales and Victoria have had railway clinics in operation for several years, and they are receiving increasing attention at the sidings.

Results of Radium Treatment

It has now been four years since coordinated Australian wide statistics have been compiled. The number of patients treated at the cancer treatment centers by means of radium or radium combined with other methods up to June 30, 1931, were: sarcoma, 113; carcinoma, 3,526; rodent ulcer, 2,915. A large

number of patients with tumors of doubtful malignancy and with benign tumors had also received treatment. Of the 3,526 cases of carcinoma, 1,731 were classified as operable. Of the patients with operable tumors, 65 per cent were alive and free from symptoms on June 30, 1931, 25 per cent showed local improvement, 3 per cent were known to have died of cancer, and in 8 per cent the patient had been lost sight of and the end result was in doubt. Of 966 patients with inoperable tumors, 14 per cent were alive and free from symptoms and 41 per cent were known to have died.

As regards rodent ulcer, of 2,652 patients whose ulcers were classified as operable, 75 per cent were alive and free from symptoms, 0.2 per cent had died, and in 9 per cent the end result had not been ascertained. Of 167 patients with inoperable and advanced ulcers, 13 per cent were alive and free from symptoms, 56 per cent showed local improvement and 32 per cent had died.

As regards sarcoma of thirty-seven patients with operable sarcomas, 43 per cent were alive and free from symptoms, 38 per cent showed local improvement and 11 per cent were dead. Of fifty-seven patients with inoperable and advanced growths, 9 per cent were alive and free from symptoms, 30 per cent showed local improvement and 65 per cent were dead.

Results of treatment by means of radium and of radium combined with other methods were good in cancer of the skin and of the lips and in operable tumors of the buccal cavity, uterus and breast.

Measurements of X-Rays

With the adoption of the roentgen as the international unit, it was left to the physicists of the national laboratories to construct standard ionization chambers with which the unit could be realized. Although the same basic principles had been adhered to there had been such individuality of design and construction that no two were exactly alike, and on account of these differences it was important to discover how closely the several standards agreed.

A small ionization chamber developed by the United States Bureau of Standards had recently been compared with the standards of Great Britain, Germany, France and the United States. (The design of this ionization chamber had been adopted by the Commonwealth Radium Laboratory in the construction of the Australian standard ionization chamber.) A summary of the results of the comparisons is given in the following table.

International Comparison of the Roentgen

Laboratory	Tube Voltage kilovolts	Half Value Layer Mm. of Copper	Ratio of Unit to Portable Unit
United States	100-140	0.10-1.10	1.000
Great Britain	110-140	0.11-0.50	1.000
Germany	100-180	0.16-1.10	1.0035
France	110	0.25	2.10
(Solomon unit)	140	0.75	2.28
	190	1.00	2.29
	190	1.40	2.30

The agreement between the national standards was as close as might be reasonably expected and was much better than that required for practical calibration purposes. The variation in the value of the Solomon unit with differences in the quality of the radiation emphasized the necessity for a "free air standard" as opposed to the "thimble" type of chamber.

As a result of the experience gained during these comparisons the National Laboratories issued recommendations that should be observed when carrying out comparisons of ionization chambers.

Radium Audit

During the past year an accurate investigation of the commonwealth government's radium was undertaken. As a result of the investigation it was stated that the radium purchased

by the commonwealth government was held in 2,169 containers with a total measured content of 10,035.36 mg of radium. The containers were distributed among thirteen different centers. Of this radium, a total of twenty-five containers with a content of 66 mg of radium had been lost in the four years since distribution was made. This loss was equivalent to 0.65 per cent of the radium over a period of four years, an average of 0.16 per cent annually.

Diploma in Radiology at Sydney University

Following the resolution made at the third conference, the senate of the University of Sydney has prepared details of a proposed course which would occupy a full academic year. The syllabus is as follows:

Part 1 One term (230 hours)

Introductory physics

Special physics dealing particularly with

(a) X-rays, radium and ultraviolet radiations

(b) The design of X-ray machinery

Laboratory practice

Part 2 Two terms (minimum 500 hours)

A Radiography, hospital and clinical practice

B Introductory course to C and D consisting of normal and pathologic cytology and special physiology

C Special pathology of conditions amenable to treatment by radiation

D Radiotherapeutic practice in recognized hospitals including work at clinics

JAPAN

(From Our Regular Correspondent)

Sept. 30, 1933

The New Law and the Dispensing of Drugs

The pharmacists have for a long time been making an effort to deprive physicians of the privilege of dispensing their own drugs but in vain. In the new medical laws, which become effective this fall, there is the following statement: "When a physician is requested to write a prescription instead of giving medicine to a patient, he shall write a prescription, so long as it is no hindrance to treatment." This is supposed to be the entering wedge to the division of the dispensing of drugs between pharmacists and physicians. The latter, of course, are not eager for a law of that kind, but public opinion, as shown by editorials in the daily papers, is for the amendment. Pharmacists have increased greatly in number since 1931. The increase in physicians has not been proportionate.

The Canadian Indians and the Japanese

It is a theory in Japan that the Canadian Indians have the same ancestors as the Japanese. Dr. S. Kobata of the Kanazawa Medical College, who attended the Pan-Pacific Science Conference, held in Canada during the summer, remained there four months that he might study this problem. On returning home he reported that, as a result of studying finger prints, blood types and palm lines, he strongly opposes this theory. He says he examined about 500 Canadian Indians and found that 70 per cent of them were of the O type blood group, only three were of the B type and none were of the AB type. The Asiatic races are mostly of the B type and but few are of the O type. Most of the Indians have arch finger prints, and but few have whorl prints which indicates that they are nearer to the white race, their palm lines are characteristic of those of a primitive race. He could not discover any sign of one and the same origin between these two races.

A Prison for Leprous Criminals

The number of lepers who violate the laws amounts annually to more than 100 and how to deal with them has long troubled the authorities. It happened this summer in the Osaka leper sanatorium that twenty-one lepers who had become Bolsheviks were set free by order of its chief, Dr. Murata. As a result of this incident it was decided to establish for the first time

a leper prison, which is to be attached to the compound of the national sanatoriums now in construction in two prefectures. For the releasing of leper radicals, strong censure was given the chief of the sanatorium.

Restriction on Specialties

In a physician's announcement, it is forbidden to advertise his ability or method of treatment, only his specialty is permitted to be shown. The term "specialty" has not been precisely defined. With the increase of so called specialties, some of the announcements have included methods of treatment, consequently, abuses have arisen. The home office, therefore, determined to restrict the number of specialties. In the new medical laws, the following only are to be permitted in physician's announcements: internal diseases, diseases of the digestive organs, diseases of the respiratory tract, diseases of the gastrointestinal tract, diseases of the circulatory organs, diseases of metabolism, neurology (or cerebrospinal diseases), epidemic diseases, surgery, surgical stomatology, splachnosurgery, orthopedic surgery, and diseases genito-urinary diseases, gynecology and obstetrics, dermatology, pediatrics, ophthalmology, otorhinolaryngology, radiotherapy (roentgen therapy) and physical therapy. Those who have devoted themselves to other branches which are not among those mentioned are warned. Because their only support is going to be suddenly cut off, they have started a movement against it. One skilled in only a single branch of treatment will indeed be hard hit, for scrofula, rheumatism, alopecia, trachoma and leprosy have been the special fields of work of some. Hereafter these will disappear from the signs of physicians.

The Eugenic Sterilization Movement

The Japan Race Hygiene Society will soon change its incorporation papers so as to enable it to start a eugenics campaign. Prof. Dr. S. Nagai, its chief, says that the society has decided to present a sterilization bill at the next session of the diet, which is expected to arouse much discussion. The bill will go beyond voluntary sterilization in order to rid Japan of unsound hereditary qualities. The details of the bill are kept secret, but diseases incurable even by medicine or punishment are to be governed by this act. As to determining who should be sterilized, an institution is to be established, and in case of opposition an appeal to the judicial court will be allowed. The method of sterilization will be simple and will not be a hindrance to marriage. The whole system will be carefully designed and adjusted to the Japanese nation.

Marriages

WILLIAM H. CHAPMAN, Blythe, Calif., to Mrs. Grace C. Houston of Ripley, in San Bernardino, August 5.

JOHN WINTHROP GAHAN, Medford, Mass., to Miss Regina Carmelita Curley of Milford, September 9.

RICHARD PHILIP HOWARD, Pocatello, Idaho, to Miss Alice Claire Nordin of Baltimore, September 7.

ARTHUR B. BARRETT, Lexington, Ky., to Miss Margaret Baker of Mooresville, N. C., October 6.

JOSEPH THOMAS CADDEN, Philadelphia, to Miss Nellie H. Orkes of Hazleton, Pa., October 13.

JEROME MILLER, Philadelphia, to Miss Beatrice V. Edson of New York, August 15.

ORLN A. BEATTY to Miss Ursula Hargadon, both of Louisville, Ky., September 30.

PAUL NEWTON MORROW to Miss Ellen Harrington, both of Philadelphia, October 4.

CLIFFORD J. STEINLE, Chicago, to Dr. AIDA SALVATI of New York, October 14.

NORMAN OSCAR LA MARCHE to Mrs. A. B. Truesdell both of Detroit, August 15.

Deaths

Robert Calvin Coffey, Portland, Ore., clinical professor of surgery at the University of Oregon Medical School, was killed, November 9, in an airplane accident. Dr. Coffey was born in Caldwell County, N. C., Oct. 20, 1869, and was educated at the Globe (N. C.) Academy and the Kentucky School of Medicine, from which he graduated in 1892. He began practice at Moscow, Idaho, in 1892, and moved to Portland in 1900. In 1908-1910 he was secretary of the Oregon State Board of Medical Examiners and in 1910 he was elected second vice president of the American Medical Association. He was a member and past president of the Oregon State Medical Society, Pacific Coast Surgical Association and the Western Surgical Association, member of the Southern Surgical Association and fellow of the American College of Surgeons. Dr. Coffey was widely known for devising a method of submucous implantation of the ureters into the large bowel for extrophy of the bladder, a method of treatment of gastro-enteroptosis, which came to be known as the "hammock operation," and was the first to remove experimentally the head of the pancreas and to reestablish functioning communication with the intestine; he also devised an operation for cancer of the rectum. He was the owner and chief surgeon of the Robert C. Coffey Clinic and Hospital, the author of a chapter on "Diseases of the Pancreas" in *Burns Regional Surgery*, and of numerous articles in various medical and surgical journals. During 1932 Dr. Coffey went abroad to address various medical societies and he was made an honorary member of the French and Italian societies of urology and surgery. He was a genial man with a host of friends and a leader among American surgeons.

Hugh Ratchford Black, Spartanburg, S. C., University of Maryland School of Medicine, Baltimore, 1883, an affiliate of the American Medical Association, fellow of the American College of Surgeons, past president of the city board of health and at one time bank president, aged 76, formerly surgeon to the Spartanburg General Hospital, Spartanburg County Hospital for Colored and the Wofford College Infirmary, formerly medical director and president of the Mary Black Clinic and Private Hospital, where he died October 8 of pulmonary embolism following amputation of the thigh for gangrene.

Charles William Moots, Mentone, Calif., Medical College of Ohio, Cincinnati, 1895, member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, fellow of the American College of Surgeons, formerly professor of surgical anatomy and clinical surgery, Toledo (Ohio) Medical College, served during the World War at one time on the staffs of the Lucas County and Flower hospitals, Toledo, Ohio, inspector of the western division of hospitals for the American College of Surgeons, aged 64, died, October 14, of heart disease.

Charles Bennett Wood, Monongahela, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1876, member of the Medical Society of the State of Pennsylvania, at one time county medical inspector, formerly on the staff of the Monongahela Memorial Hospital, for nine years member of the board of education, aged 84, died October 9 in the Hills view Farm Sanitarium, Washington, of myocarditis.

William Howard Dickson, Toronto, Ont., Canada, McGill University Faculty of Medicine, Montreal, Que., 1904, member of the Radiological Society of North America, senior demonstrator in the department of radiology, University of Toronto Faculty of Medicine, on the staff of the Toronto General Hospital, aged 55, died, October 28, of heart disease.

John Frederick Hempel, Baltimore, Baltimore Medical College, 1894, assistant commissioner of health and director of the bureau of sanitation, formerly demonstrator of osteology and clinical medicine at his alma mater, at one time sanitary inspector of the city health department and coroner, aged 69, died, October 20, of chronic interstitial nephritis.

Julian Walter Brandeis, New York, Columbia University College of Physicians and Surgeons, New York, 1899, formerly adjunct professor of clinical medicine, Fordham University School of Medicine, on the staffs of the Lebanon and Beth David hospitals, aged 68, died suddenly, October 23, of coronary occlusion.

Hugo Louis Maria Metz, White Plains, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889, member of the Medical Society of the State of New York, aged 78, died October 22 in St. Agnes Hospital, of chronic nephritis and arteriosclerosis.

Samuel Butler, West Medway, Mass., Baltimore University School of Medicine, 1904, member of the Massachusetts Medical Society, served during the World War, member of the school board, formerly on the staff of the Framingham-Union Hospital, Framingham, aged 54, died suddenly, October 16, of heart disease.

Herbert E. Truax, Miami, Fla., State University of Iowa College of Medicine, Iowa City, 1886, Hahnemann Medical College and Hospital, Chicago, 1899, Georgia College of Eclectic Medicine and Surgery, Atlanta, 1902, aged 72, died, September 13, of carcinoma of the left parotid gland.

Frank James Tuttle, Naugatuck, Conn., University of Vermont College of Medicine, Burlington, 1898, member of the Connecticut State Medical Society, aged 60, died, October 23, in the New York Post-Graduate Medical School and Hospital, of embolism and arteriosclerosis.

Simon L. Rozema, Grand Rapids, Mich., Long Island College Hospital, Brooklyn, 1886, member of the Michigan State Medical Society, on the staff of the Blodgett Memorial Hospital, aged 74, died, October 21, in the Butterworth Hospital, of carcinoma of the stomach.

Charles Otis Yenerich, Rockford, Iowa, State University of Iowa College of Medicine, Iowa City, 1910, served during the World War, formerly county coroner, member of the city council and school board, aged 45, died, October 14, in a hospital at Mason City.

Charles W. Blagden, Norfolk, Mass., College of Physicians and Surgeons, Baltimore, 1894, member of the Associated Anesthetists of the United States and Canada, aged 66, died, October 4, in the Medfield (Mass.) State Hospital, of arteriosclerosis.

Edward Bentley Cox, Louisville, Ky., University of Virginia Department of Medicine, Charlottesville, 1927, member of the Kentucky State Medical Association, aged 31, died, in October, at a local hospital, following an operation for appendicitis.

Herbert A. Arnold, Ardmore, Pa., Jefferson Medical College of Philadelphia, 1878, member of the Medical Society of the State of Pennsylvania, veteran of the Spanish-American War, aged 76, died, October 27, of cerebral hemorrhage.

James Edward McCarthy, Hubbard Woods, Ill., Rush Medical College, Chicago, 1927, formerly on the staffs of the Highland Park (Ill.) Hospital and St. Francis Hospital, Evanston, aged 34, died, October 26, of Hodgkin's disease.

John Robinson Buchan, Chicago, Long Island College Hospital, Brooklyn, 1872, Civil War veteran, aged 87, died, October 27, of toxemia and urinary retention due to carcinoma of the prostate and bladder, and hypostatic pneumonia.

Sedie Sherman Rine, Danville, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1918, past president of the Montour County Medical Society, aged 40, died, October 13, in the Geisinger Hospital, of Ludwig's angina.

Abner Oakes, South Berwick, Maine, University of Pennsylvania School of Medicine, Philadelphia, 1930, member of the Maine Medical Association, aged 29, died, October 9, in the Hayes Hospital, Dover, N. H., of septicemia.

Ernest Albert Bryant, Los Angeles, University of Pennsylvania School of Medicine, Philadelphia, 1890, fellow of the American College of Surgeons, aged 64, died, October 19, of hypostatic pneumonia and angina pectoris.

George Henry Wetzel, Sapulpa, Okla., University of Louisville (Ky.) School of Medicine, 1904, aged 51, died, September 26, in St. John's Hospital, Tulsa, of omental hernia gangrene of the intestine and diabetes mellitus.

Percy Roland Fisher, Denton, Md., University of Maryland School of Medicine, Baltimore, 1897, served during the World War, at one time health officer of Caroline County, aged 59, died, October 26, of heart disease.

Edwin Samuel Maxson, Syracuse, N. Y., Syracuse University College of Medicine, 1886, aged 72, died, October 13, in the Crouse-Ingersoll Hospital of injuries received in an automobile accident.

Milton Lavelle Munson, Los Angeles, Hahnemann Medical College and Hospital of Philadelphia, 1890, aged 80, died, September 25, of edema of the lung, cerebral hemorrhage and hemiplegia.

Arthur Wellington Rumsiselle, Washington, D. C., College of Physicians and Surgeons, Baltimore, 1877, member of the Medical Society of Virginia, aged 84, died, October 3, of nephritis.

David K. Sauls, Memphis, Tenn., Memphis Hospital Medical College, 1905, aged 54, died, October 13, in the Baptist Hospital, of peritonitis, ruptured duodenal ulcer and ruptured appendix.

George C. Brengle, Winchester, Ill., College of Physicians and Surgeons of Chicago, 1888, aged 73, died, October 10, at a hospital in Chicago, of cardiovascular renal disease.

Frederick Merwin Ives, Brewster, N. Y., University of Pennsylvania School of Medicine, Philadelphia, 1900, aged 66, died, October 28, in the New York Hospital, of brain tumor.

Hugo Toeppen, Riverside, Calif., University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1892, aged 79, died, September 26, of uremia, nephritis and myocarditis.

Arthur J. Willson, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1901, aged 57, was found dead, October 30, of poison, self-administered.

Frank Ernest Balcome, St. Paul, Eclectic Medical Institute, Cincinnati, 1899, aged 61, died, October 19, in the Midway Hospital, of cavernous sinus thrombosis.

John Joseph Magner, Hackensack, N. J., College of Physicians and Surgeons, Baltimore, 1903, aged 59, died, October 25, of chronic cardiovascular disease.

George Charles Boyer, Union City, Ind., Physio-Medical College of Indiana, Indianapolis, 1907, aged 49, died, October 6, in Anderson, of chronic ulcerative colitis.

George R. Alsop, Vincennes, Ind., University of Louisville (Ky.) School of Medicine, 1875, bank president, aged 81, died, October 2, of cerebral hemorrhage.

Jesse Chambers Hill, Rockland, Maine, Georgetown University School of Medicine, Washington, D. C., 1891, aged 75, died, September 15, of arteriosclerosis.

Elmer G. Whinna, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1891, aged 63, died, September 30, of carbuncle of the neck.

Fred L. Juett, Lexington, Ky., Pulte Medical College, Cincinnati, 1899, served during the World War, aged 65, died, October 13, of cerebral hemorrhage.

Thomas J. McGinnis, Tihne, Ky., University of Tennessee Medical Department, Nashville, 1893, aged 73, died, June 13, of uremia and chronic nephritis.

Charles E. Chase, Utica, N. Y., New York Homeopathic Medical College, New York, 1873, aged 82, died, October 10, of myocarditis and pleurisy.

Elmer Ashley Barrows, Plymouth, Mass., Dartmouth Medical School, Hanover, N. H., 1900, aged 62, died, October 18, of heart disease.

Samuel Nelson Bausman, Pleasant Hill, Ohio, Medical College of Ohio, Cincinnati, 1890, aged 73, died, October 25, of cerebral hemorrhage.

James Pinkney Waldrep, Atlanta, Ga., University of Georgia Medical Department, Augusta, 1890, aged 67, died, October 19, of asthma.

Robert Schuyler Hubbard, Bedford, Ohio, University of Wooster Medical Department, Cleveland, 1877, aged 79, died, September 28.

Clinton Willis, Brooklyn, New York Homeopathic Medical College and Hospital, 1892, aged 62, died, October 18, of heart disease.

Frank L. Southern, Philadelphia, Jefferson Medical College of Philadelphia, 1889, aged 74, died, August 7, of sarcoma of the right hip.

Frank Herbert Barbee, Memphis, Tenn., Vanderbilt University School of Medicine, Nashville, 1919, aged 38, died, July 26.

Howard Travell, New York, Albany Medical College, 1894, aged 68, died, October 17, of carcinoma of the rectum.

Daniel W. Hays, Ensign, Kan., Louisville (Ky.) Medical College, 1885, aged 79, died, October 8, in Wichita, of senility.

Oscar Michael Main, Custar, Ohio, Kentucky School of Medicine, Louisville, 1893, aged 69, died, September 11.

Frank Wilbur Chase, Des Moines, Iowa, Rush Medical College, Chicago, 1874, aged 83, died, September 9.

Joseph Perrin, Louisville, Ky., Louisville Medical College, 1883, aged 92, died, September 20, of senility.

Samuel Conway, Tulsa, Okla., St. Louis Medical College, 1867, aged 90, died, October 11, of bronchitis.

John Wesley Mitchell, Lakeland, Fla., Atlanta Medical College, 1914, aged 43, died, September 1.

Bureau of Investigation

VANNAY

Another Piece of Obesity-Cure Quackery

One of the latest stars in the firmament of obesity-cure quackery is a product called "Vannay." It is put on the market by Bio Medico, Inc., of New York City. Bio Medico is a subsidiary of McCoy's Laboratories, which puts out the so called McCoy's Cod Liver Oil Tablets. According to reports, the president of Bio Medico, Inc., is one Paul McCoy, while the treasurer and general manager is Curtis B. Brady. Mr. McCoy's claim to medical and pharmaceutical knowledge necessary for the marketing of a product for the self-treatment of self-diagnosed ailments seems to rest on the fact that he was formerly employed in the investment securities field and the furniture manufacturing line. Mr. Brady, the treasurer and general manager obtained his medical and pharmaceutical knowledge, it appears, from his connection with the publishing business.

In addition to Vannay, the obesity cure, Bio Medico, Inc. also puts out a laxative "By-Kem." There seems to be a remarkable similarity between Vannay and By-Kem if one is to judge by the advertising material. The use of the hardly parallel may be permitted.

VANNAY

Vannay Tablets developed by a group of brilliant Doctors of Science and Medicine

"These Scientists have degrees from European Universities. They have taught in leading Medical Schools and have been associated with the Pasteur Institute of Paris, France, the University of Berlin, Germany, and two leading Research Institutes of the United States. Their names are withheld for ethical reasons but their record of accomplishment is an open book."

"In Vannay they discovered a new way to combine an extract of bile in a most active form with extract of intestinal glands. It acts directly on the fat ferments (Lipases) which are fed from the liver to the intestines. By stimulating and regulating these digestive juices Vannay aids nature in her work of getting rid of waste matter."

The correct dosage is indicated on the bottle, but no two human beings are exactly alike. Some people—especially users of alcoholic beverages—frequently require an extra tablet with luncheon and dinner. You should start with the dose of Vannay Tablets called for on the bottle. If your system does not respond increase the dose or if the bowels move too often reduce the dose until your bowels move twice a day with a clocklike regularity. Remember Vannay is absolutely harmless and is not habit forming."

Before leaving the subject of By-Kem, with which this article deals only incidentally, it is worth noting that according to the McCoy advertising a number of allegedly prominent physicians connected with New York hospitals have given testimonials for this "patent medicine." The names of the physicians are not given although the hospitals are listed and physicians described as follows:

Polychinic Hospital—A well known specialist on stomach and intestines
Doctors Hospital—One of New York's best internists
Sydenham Hospital—Another well known surgeon
Lenox Hill Hospital—A celebrated internist
Mount Sinai Hospital—A specialist on stomach and intestines

BY-KEM

By-Kem is the result of years of study and experiment by a group of brilliant Doctors of Science and Medicine.

"These Scientists have degrees from European Universities. They have taught in leading medical schools and have been associated with the Pasteur Institute of Paris, France, the University of Berlin, Germany, and two leading Research Institutes of the United States. Their names are withheld for ethical reasons but their record of accomplishment is an open book."

"In By-Kem they perfected a new way to combine an extract of bile in a most active form with extract of intestinal glands. It acts directly on the fat ferments (Lipases) which are fed from the liver into the intestines. By stimulating these digestive juices By-Kem aids nature in her work of getting rid of waste matter."

"The correct dosage is printed on the bottle, but no two human beings are exactly alike. Some people—especially users of alcoholic beverages—frequently require an extra tablet. You should start with the dose of By-Kem Tablets called for on the bottle, if your system does not respond increase the dose or if the bowels move too often then reduce the dose until your bowels move with clocklike regularity. Remember it is absolutely harmless and is not habit forming."

New York Hospital—A well known urologist
Metropolitan Hospital—A prominent internist
Post Graduate Hospital—A well known specialist in female diseases
Presbyterian Hospital—One of New York's best known gastroenterologists
Harlem Hospital—A gynecology specialist
Sloane's Maternity Hospital—A famous gynecologist
Beth Israel Hospital—A prominent gastro-enterologist
Lincoln Hospital—A well known gynecologist

So much for By-Kem, the laxative put out by Bio Medico, Inc. and advertised under claims that closely parallel those made for Vannay, the alleged obesity cure. In addition to the claims already quoted for Vannay, the following are some specific claims made for this nostrum:

The Only Safe Way To Reduce
Vannay builds a healthy body while fat melts away at the very places you want to lose it.
This scientific tablet enables you to lose two to three pounds a week.
Now every woman can weigh what she will—surely and safely.

The manufacturers, in true "patent medicine" style, display the usual vagueness regarding the composition of their nostrum. They do state that the principal element in Vannay is tauro-lactic acid. They also speak ambiguously of sodium tauro-

lactate, and while the advertising matter does not actually declare that sodium tauro-lactate is the essential ingredient in Vannay, a representative of the Vannay concern is reported to have stated that it is. According to the advertising circular, there is in addition, "an infinitesimal amount of copper" together with secretine and a "blood serum lipase." In the same circular there is reproduced what purports to be a certificate of analysis by the firm of Seil, Putt and Rusby, Inc., of New York City. This is reproduced in miniature with this article. As will be seen this so called certificate is typical of those used by the "patent medicine" fraternity for the purpose of impressing the ignorant rather than of giving any information.

In newspaper advertisements one Dr. Frank S. Orland of Philadelphia is brought into the picture. Dr. Orland according to

Newspaper advertisement (Philadelphia Evening Public Ledger) of Vannay tying up with the radio spiel. In other advertisements Orland the medical director is described as an authority on overweight.

the advertisements, is "Medical Director" for Vannay and their chief radio spiel. Dr. Orland according to the American Medical Association's records was born in Russia in 1894 and holds a diploma from Temple University School of Medicine granted in 1922. He is licensed in Delaware, Pennsylvania and Ohio. Although the newspaper advertisements describe Dr. Orland as an "authority on overweight," this seems to be the only available evidence in proof of the claim. If he is such an authority the medical profession has not yet learned that fact.

There is nothing in the alleged composition of this "patent medicine" to produce a reduction in weight except those elements that stimulate peristalsis. The introduction of secretine into the formula indicates that the group of brilliant doctors of science and medicine who are alleged to have developed Vannay are not sufficiently brilliant to have learned that secretine when taken by mouth has no activity. The entire pseudo-scientific background which the exploiters of Vannay give to their product is in keeping with the modern trend in the "patent medicine" field. When scientific terms and a technical vocabulary are glibly used in the high-pressure salesmanship for

"patent medicines," the uninformed layman who may at some time or another have heard such words as ferment, lipase, chologogue, catalyzer, hormone, etc., is duly impressed.

The facts of the matter are, whatever reduction in weight may follow the use of Vannay is due to one or both of two factors. First, the laxative action ("increase the dose until your bowels move twice a day with a clocklike regularity") and, second, the requirement—common to practically every obesity cure nostrum on the market—that the victim, in taking it, should diet. Thus the purchaser of Vannay is told: "You will greatly hasten results if you go light on the fat and starchy foods that most Americans eat to excess." He is told to "cut out white bread entirely" and "favor the lean meats" and "use all the vegetables that grow above ground." In other words, eat foods of low caloric value, take Vannay until your bowels move twice a day and you will reduce in weight. Of course you will, and it hardly seems to have been necessary to call

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

THE ELLIOTT TREATMENT OF PELVIC INFECTIONS

To the Editor—In THE JOURNAL September 16 there is an article by Dr. Virgil S. Counsellor on the treatment of chronic infection of the pelvis. He tells about the use of the Elliott bag. Will you please discuss this treatment and tell me where I can buy one of these bags? Please do not print my name. M. D. Tennessee

ANSWER—The so-called Elliott treatment is a method of applying heat to the pelvic tissues by means of a distensible rubber bag, introduced into the vagina, through which water at a controlled temperature is circulated. The principle of using heat in the treatment of pelvic inflammation is, of course, not new. The vaginal douche was described by Hippocrates but was forgotten and was rediscovered a thousand years later and written about by Galen and Celsus. According to Holden and Gurnee, German physicians in the eighteenth century poured heated shot into the vagina to obtain distention and to maintain prolonged heat. Early in the nineteenth century, Emmett again advocated the hot douche in the treatment of pelvic inflammation. Gellhorn in 1924 treated pelvic inflammatory disease by means of a prolonged douche, using 2 gallons of water at a temperature of about 120 F. Gynecologists for a number of years have applied heat by means of medical diathermy. General practitioners, however, have not used diathermy generally because the apparatus was costly and special knowledge and experience with the diathermic current are necessary. Furthermore, the configuration of the vaginal mucous membrane makes it difficult to distribute evenly the heat thus generated. Some type of apparatus that would distend the vagina and flatten out the vaginal folds would bring the heat in closer contact to the diseased tissues.

The apparatus devised by Dr. Charles Robert Elliott appears to be a distinct advance over preceding methods. It consists of a distensible rubber bag which is inserted into the vagina and around the cervix, and through which a current of hot water is circulated by a small electric motor at a constant temperature regulated by means of a thermostat. This apparatus is distributed by the Elliott Treatment Regulator Company, 6 East Forty-Fifth Street, New York. In THE JOURNAL, Sept. 16, 1933, Counsellor said that the average time for a treatment is one hour, although it varies, depending on the patient's tolerance to heat. This author, reviewing the results in a series of cases treated by the Elliott method at the Mayo Clinic, concluded that a high percentage of chronic infections of the pelvis can be cured clinically by this method. There is, however, a constant small percentage of chronic infections in which operations will be required. A larger series of cases treated by the Elliott technic was reported by Holden and Gurnee before the Section on Obstetrics and Gynecology of the New York Academy of Medicine and published in July, 1931, in the *American Journal of Obstetrics and Gynecology*. In their first 150 cases treated by the Elliott method there was represented all types and degrees of pelvic disturbances and all the patients were sick enough to necessitate hospitalization. For comparison these authors selected from the Bellevue Hospital records the charts of nonoperative pelvic inflammatory cases treated before the Elliott method was taken up. They compared the pathologic observations on admission with those present at the time of discharge in the two groups of cases. The comparison showed a more rapid absorption of pelvic exudates with the Elliott method. They said that all types of pelvic inflammation of infectious origin responded equally well. There was rapid relief of symptoms in acute salpingitis and in tubo ovarian abscess. In thirty-one cases of gonorrhea of the female genital tract the patients were discharged tentatively cured after an average of 20.5 treatments for the urethra and 18.3 treatments for the cervix was given.

Attention is invited also to an article by Cosgrove in the May 1933 issue of the *American Journal of Obstetrics and Gynecology* entitled *Injuries to the Vagina Resulting from the Elliott Treatment*. The author reports four cases of damage to the vaginal mucosa—two patients having definite burns of the upper vagina and two showing complete occlusion of the vagina by cicatricial atresia undoubtedly due to original damage similar to that noted in the first two. Cosgrove advises that regular careful inspection of the parts be maintained during any course of such treatment to avoid such accidents. In dis-

Reproduction (reduced) of the Certificate of Analysis credited to Seil, Putt and Rusby, Inc. for the patent medicine Vannay. It may be counted on to impress the ignorant.

upon "a group of brilliant doctors of science and medicine" to establish such an obvious truism. But so long as the craze for slimness continues and the seekers for a short cut to that condition have money to spend, so long will "patent medicine" makers, and the newspapers and radio stations that split profits with them, continue to live off the fat of the land.

Mosquitoes Carried in Airplanes—Regular air services reach Miami, in Florida U. S. A., from Cuba, Haiti, Dominica, Porto Rico, Panama and many other places and in 1931 two officers of the United States Public Health Service determined to test whether these aircraft did or did not transport live mosquitoes. Over one hundred planes were examined on their arrival and in 20.5 per cent of cases were found to have mosquitoes on board including one *Stegomyia fasciata*. One of them proceeded to San Juan, P. R. bred some *S. fasciata* mosquitoes let them stain themselves chemically so that they could again be identified, and released 100 of them in three batches in separate airplanes. At Miami the other man waited their arrival. The journey from San Juan was 1,250 miles and took ten hours including three stops at intermediate aerodromes. At each stop the crews were changed, passengers alighted or got in mail bags and luggage were discharged and loaded. A tiffin test it would be difficult to devise but of the 100 stained mosquitoes 11 for certain were identified and 11 more were suspected of being the test ones.—*John J. Royal, Army Medical Corps* 61 268 (Oct.) 1933.

cussing this paper, Holden stated that they had given about 10,000 Elliott treatments and that only one slight burn occurred and that happened at a time when they had a substitute nurse. He recommended that moderate distention and moderate degrees of temperature be used in patients past middle life and emphasized that in all patients the vagina should be examined before each subsequent treatment to note the condition of the tissue. The distention used should always be borne with comfort by the patient. The temperature should be raised only 0.75 degree per minute and should not exceed 130 F.

DANGERS OF NICOTINE SPRAY

To the Editor—Would you kindly tell me whether there are any harmful effects on a worker using nicotine spray in greenhouses? Also are there any means of prevention of nicotine poisoning to such workers?

JOHN A WAHLEN M.D., Montebello Calif

ANSWER—Nicotine sprays, as used in greenhouses, are a practical source of chemical dermatitis. It is not fully established that the nicotine itself is the offending agent. Other substances used along with the nicotine may be responsible.

In addition, it is well established that contact with any one of several varieties of greenhouse plants may be followed by chemical dermatitis.

Nicotine has been credited with such properties as to permit of skin absorption which may be followed by systemic poisoning. This is neither affirmed nor denied but is regarded as possible.

The atomization of nicotine sprays may lead to some intake into the lungs. As tobacco dust containing nicotine entering the lungs may lead to harm there is every reason to accept the possibility of nicotine poisoning from this source. As the minimum lethal dose of nicotine for a human being approximates 0.065 Gm, much smaller quantities may be expected to produce ill effects.

For workers much engaged in this operation it seems desirable to recommend the wearing of light respirators of the filter type. The wet sponge variety is perhaps the simplest and most practical. In addition, the wearing of liquid proof gauntlets may be advantageous.

This reply contemplates theoretical possibilities. It is well known that many thousands of greenhouse workers and home gardeners use nicotine sprays without any known ill effects.

TREATMENT OF CONCRETE BURNS

To the Editor—We are having many cases of concrete burns at a construction company in London W. Va. These burns are painful and are seen chiefly in hot weather when there is excessive perspiration. I am anxious to find a way to prevent the burns and also would be pleased to have any advice concerning the prevention and treatment of them. Eucalyptol solution with a little phenol to relieve the pain seems to act fairly well.

E. B. THOMPSON M.D., Montgomery, W. Va.

ANSWER—Concrete burns primarily are to be attributed to the alkali action of the calcium oxide entering into the concrete. Nearly 60 per cent of the concrete is calcium oxide. In addition to the chemical burns, furunculosis, resulting in part from the plugging up of sebaceous glands, is common.

In the U. S. Public Health Service study of the Health of workers in the Portland cement industry (Bulletin 176, 1928) it is noted that 62 per cent of all disabling skin disorders in this industry resulted from furunculosis.

The chemical burns may vary in severity from minor dermatitis to extensive second degree burns, the latter usually arising after the entry of concrete into the boots followed by failure immediately to remove the concrete. In addition, the entry of concrete into the eyes may lead to major injury.

In all skin injuries from lime and similar alkalis, slow healing is to be anticipated because the tissues damaged are likely to form a toughened "eschar," which acts as a foreign body until decomposed or removed. On this account tannic acid (so valuable in the treatment of many types of burns) is not always indicated.

By way of prevention of skin injuries, the following are suggested:

1. Tenacious oily substances, such as petrolatum or hydrous wool fat, should be applied to exposed portions of the skin.

2. All exposed portions of the body, particularly those on which dust settles, should be washed one or more times during the work day, in addition to the complete bathing at the end of the work period. In this washing, harsh soaps should be avoided. Oily substances should be reapplied.

3. Leather and rubber gloves should not be used, unless these effectively protect against the entry of any mixed concrete or dust.

4. At the beginning of any irritation, or after extensive exposure conducive to prompt irritation, flushing of the exposed area immediately should be provided. Sodium bicarbonate solution in the presence of lime will act as an acid, and constitutes a simple neutralizing agent. Dilute acetic acid may be of some value.

5. Cessation of further exposure for all workers presenting any degree of lime injury is desirable.

For the purposes of treatment, the following items are suggested:

1. All fresh burns should be treated by extensive lavage with water.

2. Mechanical rubbing off of damaged tissue should be done, particularly on the first day of the burn, and possibly on the second and third days. This may be a painful process, but it shortens the period of disability. At times a local anesthetic may be desirable.

3. Wet dressing with weak acids may be serviceable. The use of bntesin picrate ointment tends to relieve pain, through the anesthetic action of bntesin. This ointment is contraindicated for a few persons whose skins are irritated by this medication.

Further discussion of all aspects of alkali burns may be found in the publications cited below:

HEART BLOCK—PULSATING ANEURYSM

To the Editor—1. I have a patient aged 27, a fleshy woman with heart block shown by electrocardiogram. Aside from rest what treatment may be of value? She has menstrual difficulties. Would glandular preparations including thyroid, be contraindicated? 2. A man aged 43 with a history of a chancre twenty-three years ago has pulsating aneurysm. The blood pressure is 160 systolic 60 diastolic. What treatment aside from iodides is indicated and in what form? Would mercury and bismuth compounds be dangerous? In case of women would iodides be of value? Please do not publish my name.

M. D. Oklahoma

ANSWER—1. It is not stated whether the heart block is complete, partial or merely a delay in conduction time, or particularly whether it is accompanied by symptoms. The cause should be sought, such as syphilis or previous infectious disease. In established, symptomatic block, no treatment may be required beyond reasonable restriction of activity. The weight should be reduced to the average normal for the patient's age and height, primarily by dietary measures. The present caloric intake should be estimated and a diet of substantially lower caloric value substituted. Fats and, to a lesser extent, carbohydrate must be materially reduced, protein need not be restricted. The daily food allowance should include one or two eggs, two glasses of skimmed milk or buttermilk, ample leafy vegetables, fruit and lean meat, restrictions should be placed on butter, cream, fat meat, sugar, bread and cereals. A weight chart should be kept. Desiccated thyroid gland may also be used, starting with 0.13 Gm daily and reducing to 0.065 Gm if tachycardia or tremor of the fingers develops. These measures may correct scanty, delayed or irregular menses. Since the nature of the menstrual difficulty is not stated, further advice cannot be given.

2. In the patient with aneurysm due to syphilis, both potassium iodide and preparations of mercury should be used. Beginning with ten drops three times daily saturated solution of potassium iodide may be increased one drop daily to thirty or forty drops per dose. Mercury compounds may be used in any form except intravenously or intramuscularly. Other treatment varies with the individual case, depending particularly on the condition of the coronary arteries and myocardium. After initial treatment with iodides and mercury, neosarsphenamine may be used cautiously, beginning with small amounts (from 0.025 to 0.1 Gm) and gradually increasing to moderate doses if no reactions occur.

A compound that seems to give good results is bismuth arsphenamine sulphonate. This is given intramuscularly at intervals of from three to seven days, beginning with a small dose and gradually increasing to 0.2 Gm to a total of from forty to eighty injections. It must be emphasized that individualization is necessary. The subject is discussed in general by Christian (Oxford Monographs on Diagnosis and Treatment 3: 235) and in more detail by Stokes (in *Tices Practice of Medicine* 3: 428a).

INDUSTRIAL HAZARDS FROM NITROGEN OXIDES
OR BLACK POWDER EXPLOSIONS

To the Editor—A man aged 33 a coal miner was at work and the mine was using Black Pellet Powder. About fifteen to twenty minutes after a blast the patient with three or four miners entered the compartment which had been blasted and they all loaded a car of coal, taking about fifteen minutes. After that time he was suddenly nauseated, dizzy and dyspneic. He was taken home where I saw him from four to six hours later. The temperature was 101 F. The pulse rate was 118. The blood pressure 120 systolic 78 diastolic. He complained of dyspnea and dizziness and of a sharp pain in the left lower anterior part of the chest, especially with a deep respiration. Next day the temperature was 103 F., respiration 36 and blood frothy sputum appeared. The pain persisted in the same part of the chest. Respiration was shallow and rapid. The patient vomited several times. Examination revealed no abnormal signs. The head, eyes, ears, nose, neck and mouth showed no pathologic changes. The heart was regular in rate, rhythm and force. The borders were within normal limits. There was no precordial activity and no palpable thrills could be detected. Examination of the lungs showed questionable impaired resonance at the lower left lung field. Auscultation revealed normal breath sounds. No pathologic changes were elicited in the abdomen. Four other men are known to have had a similar experience at different times. Do you know of any incidents contained in the blasting powder that might cause the picture? Please omit name. M D Ohio

ANSWER—The picture presented strongly suggests the likelihood of injury by nitrogen oxides. Only occasionally are these gases produced after mine blasting with black powder. Faulty detonation of the charge resulting in the burning of some or all of the powder, rather than a quick explosion, is the common source of this gas in mines.

Carbon monoxide may have produced some of the manifestations at the onset of the condition, but subsequent developments are characteristic of a mild intoxication from nitric oxide or other nitrogen oxide. Comparison should be made between the symptoms cited and those characteristic of this injury. These include dyspnea, coughing, vomiting, dizziness, difficulty in walking, pain in the chest and pain in the abdomen. After a period of a few hours of increasing comfort, all are exacerbated and accompanied by fever, prostration, expectoration of bloody fluid, pleuritic pains, rapid respiration and pulmonary edema.

Explosion of black powder may form potassium carbonate, potassium sulphate, other sulphur compounds, carbon dioxide, carbon monoxide and various oxides of nitrogen. One or more of these gases account for any occupational injury that arose under the conditions described in the query. Pain in the left lower part of the chest together with dyspnea, nausea and tachycardia, are common symptoms in the neuroses so common after exposure to carbon monoxide in low concentrations.

HEADROLLING

To the Editor—My boy aged 7 years has rolled his head at night when asleep all his life. He is worse now than ever in that his shoulders and whole body roll and he has added another one now. I told him to lie on his face so that he would not roll his head and I would give him a bicycle but he brings his leg up and brings down the leg with a resounding whack that wakens me in the same room. These rolling and thumping movements do not take place before midnight unless he has been awakened partially and is going to sleep. After midnight until morning off and on the movements continue as much as five minutes at a time. It is worse when he sleeps lightly and worse from 4 o'clock on. He also does it at first on going to bed to put himself to sleep. Punishments have no effect, waking him up has no effect, promises of prizes has no effect. He is otherwise well and is a bright boy and learns things readily at school. There is no insanity in the family on either side. He has had cod liver oil, eggs and a proper vitamin diet and there are no other signs of rickets save that he sweats considerably—more than normal—before 12 o'clock at night mostly on first going to bed. I should like to break him of the habit. Can you give me some advice? I find nothing of help in Kerley's book (New York) or Griffiths (Philadelphia) both child specialists. Kindly omit name. M D, Shantung, China

ANSWER—A condition similar to the one described is not identical with it as has been mentioned in the literature by various authors. Oppenheim has described an involuntary nocturnal movement of the head which he observed that was tic-like in character. He described the condition as a "sleep tic." Zappert described the condition as nocturnal jactitation of the head. These head movements are often rhythmic and occur with considerable force during sleep. In some instances movements become more rapid and finally the head moves like that of a dancing dervish though the patient continues to sleep. This condition may remain unchanged for years. Other cases have been described in which the rotatory movement was first confined to the head and later the trunk and extremities participated.

This nocturnal rolling of the head is neither a tic nor a nodding spasm for these do not occur during sleep. Zappert considers the condition one of stereotyped movements which from long and repeated continuance become automatic as do

thumbsucking and nailbiting. It is difficult to advise about treatment though the general advice concerning nervous children should be applied: a quiet life, avoidance of excessive mental stimulation, healthful play and exercise with avoidance of excessive fatigue, hot baths at bedtime, and a course of treatment with either bromides or phenobarbital.

References to this condition may be found in *Abt's Pediatrics* volume 7, chapter CLXXIII, contributed by Dr. George Hassin p. 306, also *Die Nervenkrankheiten des Kindesalters* by Peritz, Berlin, and J. Zappert (*Jahrb f Kinderh* 42 70, 1905).

TREATMENT OF STERILITY

To the Editor—A woman aged 35, physically normal in all respects married five years is desirous of having children. Physical blood urine and gynecologic examinations have all been negative except that she excretes too many female sex hormones in the urine just prior to menstruation. The basal metabolism is normal. She has had two dilations and curettements and one dilation with insertion of a Wythe drain for two weeks. The Rubin test is negative. She has taken progesteron both by mouth and hypodermically daily ten days before menstruation. Neither preparation has helped the dysmenorrhea or the sterility. She has never had an orgasm. What would you suggest to make the patient pregnant? Her husband is healthy. Examination of the semen showed normal spermatozoa. Please omit name and town. M D Pennsylvania

ANSWER—The treatment of sterility is not easy, especially in a case in which the conditions are as normal as in the one described. It is not clear what is meant by "She excretes too many female sex hormones in the urine." It is assumed that the statement "The Rubin test is negative" implies that the tubes are patent to gas, else of course this test should be repeated and perhaps also iodized oil should be used to detect a possible block in the tubes. Of course, if the tubes are definitely impermeable, only an operation such as salpingostomy or tubal implantation may help overcome the sterility. As is well known an orgasm is not essential to fertility. Preparations of female sex hormones are seldom effective in sterility cases, and even when it seems to be responsible for conception, large doses are required. Nothing is said concerning the weight or height of the patient. In spite of the normal basal metabolic rate, small doses of thyroid should be given over a period of a few months.

Even though the spermatozoa are normal, they may nevertheless not be able to reach an ovum in the tube. The physician should first examine the semen as it is obtained from the vagina immediately after intercourse to make sure that the sperm remain alive in the vagina. But, more important still it is essential to aspirate the cervical secretion shortly after intercourse to make sure there are motile sperm in and beyond the cervical canal. Not infrequently there is a cervical barrier to spermatozoa and this may be due to cervicitis or a thick mucous plug. If the latter conditions are present, they must of course be treated. If in spite of treatment live spermatozoa are found in the condom specimen but not in the vagina or the cervix, insemination may have to be performed. This must be repeated a number of times during each intermenstrual period under aseptic precautions. Thus far insemination has had only a limited field of usefulness in human beings.

Alkaline douches just before coitus are sometimes effective.

INJURIES AFTER SPINAL ANESTHESIA FOR
CURETTEMENT

To the Editor—A patient was admitted to a hospital because of incomplete abortion. A curettement was performed under spinal anesthesia (procaine hydrochloride 100 mg in 4 cc of fluid) and the uterus was apparently scraped clean. About thirty hours later the patient complained of pain over both internal malleoli and on examination there was noted several vesicular formations over each internal malleolus. The appearance of the surrounding tissue did not suggest a burn of a physical or chemical nature. Careful questioning of the floor and operating room nurses did not present any enlightenment as to the cause. The vesicles were ruptured and evacuated of the clear serous contents and healing progressed fairly well. Laboratory data including the Wassermann report were negative. The appearance was highly suggestive of some nerve involvement as one sees in herpes zoster. Is it possible that the formations could be attributed as an unoward sequel to the spinal anesthetic? If so please give data as to references. Please omit name. M D Ohio

ANSWER—The pain and vesicles that appeared on the internal malleoli almost certainly had nothing to do with the spinal anesthesia. Herpes zoster is the most likely diagnosis. The administration of spinal anesthesia is rather heroic for such a simple operation as a curettement. In such a case the anesthetic carries much more risk than the operation itself. If the surgeon wants to avoid a general anesthetic he can easily perform a curettement under direct infiltration anesthesia, which is far safer and simpler than spinal anesthesia.

STOKES ADAMS SYNDROME WITH ARTERIOSCLEROSIS

To the Editor—I have been treating an elderly woman for hypertension by the use of sodium nitrite (previously having used potassium iodide) and a salt free diet. She has had strychnine one fortieth grain (16 mg.) at intervals because of a slow pulse. At times she has spells of everything going black and will fall if she is standing at such times. The blood pressure is 200 systolic 80 diastolic. The heart rate ranges from 40 to 80. The urine is normal. She has developed a generalized edema of the mucous membranes. The mouth is red and sore the uvula is red and swollen and there is burning on urination. There is soreness over the urinary bladder. There is diarrhea causing burning. There is no fever and the patient is not acutely ill but of course she is uncomfortable. What could cause this generalized condition of the mucous membranes? Is there a lack of something in the diet? Any suggestions will be appreciated. Please omit name.

M D Washington

ANSWER—That the attacks of transitory loss of consciousness associated with a variable heart rate as low as 40 represent the syndrome of Stokes-Adams is quite clear. The high pulse pressure suggests aortic insufficiency or if recorded during the period of slow heart rate, quite typical of the blood pressure in heart block. General arteriosclerosis is no doubt an important factor and may be the essential cause.

The proper interpretation of the other symptoms is difficult from the information given. It does not seem reasonable to associate these with the cardiovascular phenomenon unless arteriosclerotic Bright's disease with failure of renal function and retention acidosis can be assumed. Arteriosclerosis of the mesenteric vessels with resulting diarrhea is a possibility. With loss of fixed base, acidosis with the mouth and urinary symptoms might occur.

Other diseases associated with diarrhea, sore mouth and tongue are pernicious anemia, and the vitamin deficiencies pellagra and sprue.

That the treatment employed can be the causal factors is most unlikely. Potassium iodide is certainly not at fault and sodium nitrite in therapeutic doses will not cause diarrhea or toxic symptoms such as those described.

PREVENTION OF CLUMPS IN BARIUM SULPHATE MIX

To the Editor—It has frequently been noticed that after the administration of a barium meal there has been difficulty in eliminating the accumulated barium sulphate which seems to form concretions in the intestinal canal which when broken present a yellowish white color and a noncrystalline cleavage. As the barium sulphate is given in an unpalatable powder form and is practically insoluble in the body acids and alkalis the question has come up regarding the agglutinating factor. Can you give any information on this point? Please omit name.

M D, Minnesota

ANSWER—The formation of concretions may possibly be lessened by the addition of an indigestible colloid such as Karaya, of which 5 per cent may be mixed with the usual dose of 150 Gm of barium sulphate, which is shaken with 500 cc of water just before taking. It not only keeps the powder in excellent suspension but it also seems to make the evacuation easier by softening the stool. Agar has a similar effect but is not quite suitable for the purpose. The agglutinating factor is possibly mucin.

ARSENICAL DERMATITIS

To the Editor—A man aged 27 on physical examination was entirely negative except for an arsenical dermatitis of one year's duration which he contracted in a plant where arsenic is used. He has been under the care of several physicians and at present has had nine remissions and exacerbations. Itching is almost unbearable and is most severe over the perineal region and especially the scrotum. Irritation caused by light exercise or warm weather intensifies the symptoms. My treatment has been sodium thiosulphate by mouth, rest, soda and colloid baths, dusting powders, calamine lotion and daily intravenous injections of sodium thiosulphate 15 grains (1 Gm.) each. After one month of this treatment he was symptom free. The dermatitis had disappeared and he felt well and strong. The intravenous medication was then discontinued and a week later his dermatitis began to recur. Returning to intravenous sodium thiosulphate three injections have again caused marked improvement. I should like you to answer the following questions: Is the treatment acceptable? What are his chances for a permanent recovery? Could you direct me to some literature on this subject? Any suggestions you will give me will be greatly appreciated. Kindly omit name.

M D Minnesota

ANSWER—The treatment outlined is satisfactory for a case of dermatitis due to arsenic. In view of the numerous exacerbations, presumably without further exposure to arsenic care should be taken to exclude other causes particularly external irritants. Stokes has pointed out the advisability of removing any chronic foci of infection especially in the tonsils and teeth as this factor seems to play an important part in some cases of dermatitis of this type. This procedure should however, be carried out with caution as it may cause a severe flare-up in the skin condition.

The chances for permanent recovery are good, but the skin may remain irritable for weeks or months, so that recurrent attacks of dermatitis, usually patchy in type, may occur.

Among the numerous articles dealing with this subject are

- McBride W I and Dennis C C Treatment of Arsenamine Dermatitis and Certain Other Metallic Poisonings Arch Dermat & Syph 7 63 (Jan) 1923
Osborne E D Microchemical Studies of Arsenic in Arsenical Dermatitis Arch Dermat & Syph 18 37 (July) 1928
Ullmann K Dermat Wchnschr 82 11 (Jan 2) 1926

TREATMENT OF STOMATITIS IN
PERNICIOUS ANEMIA

To the Editor—Please inform me of the latest treatment for stomatitis or sore mouth in pernicious anemia. A patient seems to have normal blood with the exception of a few sickle cells. Her strength and blood count are good but the sore mouth still persists in spite of all medication. She scarcely can eat anything but bland liquids. She is now taking liver, stomach and dilute hydrochloric acid.

C GLENN WHITE M D San Diego Calif

ANSWER—It is unusual for a sore tongue to persist in a patient with pernicious anemia after the blood has reached normal limits. When this does occur it may be the earliest evidence of a relapse and, therefore, be an indication for increasing the dose of liver extract or desiccated hog stomach. There is no specific local medication for this condition although the application of a 1 per cent solution of silver nitrate for two or three days may give temporary relief. The dilute hydrochloric acid should be omitted for several weeks as this may aggravate the glossitis.

IRRADIATION IN TUMOR OF CAROTID BODY

To the Editor—I recently saw a patient with a tumor mass in the left side of her neck which I diagnosed as a tumor of the carotid body or peritheloma. It is now the size of a small hen's egg and is freely movable from side to side but not up and down. It is firm smooth and not nodular. It has given little pain but it pulsates with each beat of the heart. Would you advise x-rays, biopsy or attempted removal?

WILLIAM LOOMIS POMEROY M D Waycross Ga

ANSWER—It is not wise to irradiate a tumor of which the nature is not known for if the nodule should prove to be radio-resistant this might prevent recourse to surgery later because of interference with healing from the tissue injury. If as seems probable, the growth is from the carotid body, surgical removal is advisable for in a considerable portion of such tumors a permanent cure is obtained after a complete excision. If there should be a recurrence, then the question of irradiation, whether by x-rays or by radium may be considered.

TREATMENT OF VARICOSE ECZEMA

To the Editor—A woman aged 70 otherwise in good health has had varicose veins of the legs for many years. For the last five or six years a patch of eczema has developed in the region of the right ankle about 3 inches in diameter which itches so intensely that it often bleeds as a result of scratching. Numerous antipruritic lotions and ointments were advised by several prominent dermatologists and were used as were also starch and soda baths. Unna's paste stimulating preparations such as liquid tar also liquor alumin acetatis the oral administration of bromides and calcium gluconate. She has worn elastic handgrips. None of these measures allayed the itch. Control of her diet combined with rest in bed for four weeks and the local application of a liquid tar preparation did heal the eczema and gave considerable relief but soon after she was on her feet again the eczema and the pruritus returned. An emment uregon injected and obliterated all the visible and palpable veins of the right leg and thigh about six months ago with some improvement for a short time but the eczema and intense itching have returned now and are as severe as originally. There is a similar condition of the left ankle but not as marked. The blood sugar urea creatinine and uric acid have been normal on several examinations. Urinalysis is normal. The blood pressure is normal. The blood vessels are not sclerotic. The Wassermann reaction is negative. Would you advise roentgen therapy over the eczematous area? Can you suggest anything further in the way of treatment? Kindly omit name.

M D Pennsylvania

ANSWER—The condition described seems to be a varicose eczema. One wonders about the possibility of a superimposed ringworm infection, the diagnosis of which could be easily made by the examination of scales. The varicose veins should be completely obliterated from the groin to the ankle. If necessary, a high saphenous vein ligation can be made eliminating further venous backpressure on the irritated area of skin. Locally the application of a lotion containing fuchsin 1 Gm, phenol 5 Gm, alcohol 10 Gm, and distilled water, 100 Gm may soothe the itch. But a continuous, systematic compression with Unna's boot or an elastic adhesive dressing is most important. The dressing must be changed weekly and continued for a long time. If all other methods fail, small doses of x-rays (from 100 to 125 roentgens with a heavy filter) can be administered by a cent

petent roentgenologist The fact that one is dealing with a chronic and quite resistant type of lesion requires a great deal of patience The patient should be in the hands of a man experienced in this line, and she should not be shifted from one physician to another A physician's mother is often apt to be the victim of too many suggestions

CAST ON PARALYZED LEG

To the Editor—Would it be good treatment to apply a plaster cast to a paralyzed leg and should this be done early? Would a proper fitting brace applied to the paralyzed leg be better than a plaster cast? Should it be applied as soon as the child is fit to be out of bed? Please omit name

MD Pennsylvania

ANSWER—The data given are insufficient in that mention is not made of the stage of the disease, the presence or absence of deformity, pain and sensitiveness

It is good treatment to apply a plaster-of-paris splint or a light cast to the paralyzed leg A properly fitting brace has many advantages over a complete plaster-of-paris cast in that it is removable, thereby permitting the use of physical therapy, including radiant heat, very gentle massage, guarded active and passive movements, electrotherapy, hydrotherapy including underwater gymnastics, and heliotherapy by sun or ultraviolet lamp

IMMUNITY TO TYPHOID AND USE OF CONVALESCENT SERUM

To the Editor—1 What is the serologic or immunologic explanation of why blood or serum from either convalescent typhoid patients or individuals recently immunized against typhoid is not given as treatment in typhoid? 2 Does intravenous injection of typhoid vaccine create a positive Widal test and if so does the positive Widal test induced develop much more rapidly and of higher titer than that induced by ordinary subcutaneous injection of the vaccine? 3 Is there a parallelism between the Widal test and clinical immunity to typhoid?

R M PURDIE MD Houston, Texas

ANSWER—1 There is no serologic or immunologic explanation why the serum or blood of typhoid convalescents or of persons recently immunized against typhoid is not used for treatment—it just has not been done except possibly in a few cases

2 The intravenous injection of typhoid vaccine, which might be dangerous, will call forth specific agglutinins, and under comparable conditions probably more rapidly and more profusely than the subcutaneous injection

3 The presence in the blood of agglutinins for the typhoid bacillus indicates a degree of immunity to typhoid infection but not necessarily absolute clinical immunity under all conditions

DISAPPEARANCE OF SPERM AFTER VASECTOMY

To the Editor—A patient has had a bilateral vasectomy How long does it take before the spermatozoa disappear from the semen in other words before the patient is sterilized? Kindly omit name

MD, North Dakota

ANSWER—There are no definite statistics available as to how long a time is required for spermatozoa to disappear from the semen following bilateral vasectomy It is known that the secretions from the various parts of the genital tract have much to do with the activity of the spermatozoa, and in the absence of such secretions the motility of the spermatozoa is likely to be retarded In all probability one or two ejaculations should be sufficient to remove spermatozoa from the semen following bilateral vasectomy

IMMUNITY TO DIPHTHERIA

To the Editor—An adult with a positive Schick test has been given toxin antitoxin twice One cubic centimeter of toxin antitoxin at weekly intervals for three doses was given each time One year after the last immunization the Schick test is still positive The sensitivity test for toxoid is also strongly positive What procedure should be used to render this individual immune to diphtheria? Please omit name

MD West Virginia

ANSWER—In some adults who are highly sensitive to proteins it is difficult to be certain whether a Schick test is positive or not In such cases it is helpful to estimate the amount of antitoxin in the blood by Romer's method If the blood contains 0.03 or more unit of antitoxin per cubic centimeter, the person is immune and the apparently positive Schick test may be disregarded This estimation requires the use of guinea-pigs and is not practical outside a laboratory However, persons are occasionally found who continue to give positive Schick tests after repeated series of injections of toxin-antitoxin They appear to lack the ability to elaborate antitoxin The knowledge that they are susceptible to diphtheria should lead them to secure prompt advice in case of sore throat and so to obtain early administration of antitoxin in diphtheria should occur

COMPATIBILITY IN PRESCRIPTION

To the Editor—Please tell me if there are any contraindications to the use of a mixture of solution of potassium arsenite and mercuric chloride (sufficient mercuric chloride for a 1:5000 solution) in Vincent's infection Are there any chemical reasons why these preparations should not be combined? I have employed this mixture to some extent and it appears to be more efficacious than the solution of potassium arsenite alone

S J Lewis MO Augusta Ga

ANSWER—When the two are mixed a grayish precipitate forms obviously because of the alkalinity of the solution and the formation of black mercurous oxide the mercuric salt is evidently reduced A solution of arsenic acid is compatible with mercuric chloride and might for that reason be preferable

CASES OF HYDROCEPHALUS IN ONE FAMILY

To the Editor—I note in THE JOURNAL September 23 page 1020 a query concerning the birth of more than one hydrocephalic child to the same mother I agree with you that such an occurrence should be recorded in medical literature were such an event always recorded one could with more certainty make adequate predictions as to the chances of its occurring in any family in which one hydrocephalic child has already been born

As to some of the references to similar events I would call your attention to the following which have been picked up by me in the course of my reading and probably represent only a small part of the references that might be found if one made an extensive survey of the literature

Allingham (Lancet 2 1866 1904) reported one woman as having had twelve pregnancies four of which were miscarriages and five normal There were three premature hydrocephalic children The thirteenth pregnancy resulted in a hydrocephalic infant from whose head 6 pints of fluid was removed

Andersen (Am J Obst & Gynec 9 382 [March] 1925) reported two of three children hydrocephalic

Popham (Lancet 1 1829, 1906) recorded the case of a man who by his first wife had one infant with hydrocephalus one with spina bifida by his second wife one with hydrocephalus and one with anencephaly

Straub (Arch f Ross u Gesellsch f Biol 14 199, 1922) found a case in which a man had married his niece and had one child with hare lip and club hands and feet and two others with hydrocephalus as well as malformed hands Two were normal

Wetterwald (Rev franc de gynec et obstet 19 668 1923) reported the birth of two male infants with hydrocephalus and malformed genitalia

Wiener (Zentralbl f Gynak 30 706 1906) reported an instance in which the first and third children had hydrocephalus

This list incomplete as it is nevertheless shows that when once a woman has given birth to a hydrocephalic infant she may do so again If she has done so twice as was the case in the report from your correspondent from Massachusetts it is evident that the combination of hereditary factors necessary to produce hydrocephalus is one easily obtainable in that mating Therefore such a couple would run a grave risk of having other children in the family reproduce the same defect

Moreover hydrocephalus is a defect that is not infrequently found with spina bifida and sometimes with clubfoot, frequently with both defects Should subsequent offspring not have hydrocephalus they might easily show the other defects Your correspondent has answered his patients wisely

MADGE THURLOW MACLEIN MD London Ont

TREATMENT OF SPINAL CORD LESIONS IN PERNICIOUS ANEMIA

To the Editor—In reply to a question on this subject (THE JOURNAL September 30 p 1099) it should be pointed out that an adequate amount of the antianemic substance is that amount which is sufficient to maintain the blood at a normal level with an excess above this to influence favorably the spinal cord lesions It is not sufficient to maintain the red blood cell count at a level of between 4.5 and 5 million per cubic millimeter because spinal cord lesions will progress at such levels Counts of 5 million cells or even much higher should be maintained for best results as I have pointed out elsewhere Such levels are best maintained and improvement perhaps is more striking with the use of liver extract administered parenterally as has also been pointed out (Am J M Sc 186 271 [Aug] 1933) The importance of regulated and controlled exercises designed to retrain the affected muscle groups and to improve the balance has been emphasized in an article in the New England Journal of Medicine (209 329 [Aug 7] 1933) and elsewhere Such training should be emphasized as opposed to exercise as generally suggested

In your answer to a question by Dr William L Nute in regard to the administration of iron in secondary anemia (THE JOURNAL September 23 p 1019) no mention is made of the use of those iron salts which have recently been shown to be the most efficient The preponderance of evidence favors the use of the more readily soluble or of the ferrous salt Ferrous ammonium citrate (L S P) may be used either in solution or as the dry powder which is available in finely powdered form in capsules (Lederle Laboratories) Ferrous carbonate (L S P) may be given conveniently as Bland's pill The need for large doses (3 Gm daily) should be emphasized Doses of 0.2 Gm of reduced iron three times daily can hardly be considered adequate dosage

California July Examinations

Dr Charles B Pinkham, secretary, California State Board of Medical Examiners, reports the written examinations held in San Francisco, July 11-13, 1933, and in Los Angeles, July 25-27. The examinations covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. Two hundred and seven candidates were examined, 202 of whom passed and 5 failed. The following colleges were represented:

Book Notices

How to Stay Young By Robert Hugh Rose A B M D Cloth Price \$1.50 Pp 195 New York & London Funk & Wagnalls Company 1933

Here is a book that is full of facts and almost as full of erroneous deductions from them. No one can deny the importance of diet as a hygienic factor, but, on the other hand the author will find few who will agree with him that merely by eating properly one can make 70 the prime of life even though Chauncey Depew, Thomas A Edison, Henry Ford, John D Rockefeller, Clemenceau, Hindenburg, Mellon and other distinguished moderns have expressed their opinions to that effect. The author quotes their interviews frequently from popular lay periodicals. He lays great stress on the sixteenth century writings of Louis Cornaro whom he calls the father of life extension. He stresses the alleged longevity of Bulgarians and concludes that fermented milk is the cause of their long life. He proposes that by combining the good features of New Zealand's healthy regimen with those of Bulgaria we could extend our own average length of life and increase the proportion of our population to 90 or 100 years of age. In a chapter entitled 'Eat Your Way to Youth' he says that nutrition 'is the most important factor in maintaining youth and prolonging life'. The diet that he recommends is an excellent one, laying proper emphasis on milk, fruit, green vegetables and variety. He does not fall into the fallacy of vegetarianism or any of the more grotesque dietary fads. There is so much good in the book that it is unfortunate that he has overemphasized diet and that in writing to his title he has whether consciously or not produced a work which will undoubtedly have a sales appeal at the expense of scientific accuracy.

Part two of the book is worse than part one. Here he extols methods of rejuvenation including gland grafting and then attempts to link faulty diet in a causative relationship with endocrine disturbances. He attributes the prevalence of gastro-intestinal carcinoma to faulty diet. He overemphasizes the effectiveness of vaccines in the prevention of colds. In a chapter on moderation he emphasizes the importance of the golden mean but he does not seem to be able to observe this principle in arriving at conclusions from unquestioned facts.

A Study of Rural Public Health Service for the Committee on Administrative Practice of the American Public Health Association by the Subcommittee on Rural Health Work Edited by Allen W. Freeman M D Cloth Price \$2.50 Pp 235 New York Commonwealth Fund London Oxford University Press 1933

The Committee on Administrative Practice of the American Public Health Association sponsors this study of health work in rural regions in the United States. The material is based on a study of forty-six counties which were surveyed in detail by field workers for the committee. Of these, twenty-seven were organized that is to say, had an organized county health department under the direction of a full-time medical health officer, with a staff of one or more nurses, inspectors, clerks and other full-time employees. The remaining nineteen counties were unorganized having various types of part-time health service or virtually no health service except in name. In addition a questionnaire was sent to 467 county health officers in thirty-four states where a full-time county health service was in operation in 1929, and 337 counties, including the twenty-seven surveyed, supplied information suitable to permit of tabulations. In a brief review it is impossible even to mention all the activities that have been surveyed or the conclusions arising from the survey. In general the study developed what might have been expected, that counties with full-time health organizations get better health service than those without, and also spend more money for health promotion. Even in the best organized counties where the newer health promotion activities have been developed such as maternal and infant hygiene and school health supervision there still remains much to be accomplished in elementary public health activities such as general sanitation, communicable disease reporting and control, reporting of vital statistics, and control of food and water supplies. Of the 3000 counties in the United States, only about 500 have reasonably well organized public health service. In the others, such service remains to be developed. The committee study did not take into consideration public health work done by county medical societies. Presumably this is not a significant factor in rural regions. It is in precisely these areas that the family physician will find the best opportunity for extending his practice in the fields of preventive medicine and public health.

The Health of Workers in a Textile Plant By Rollo H. Britten Senior Statistician J J Bloomfield Sanitary Engineer and Jennie C. Coddard Junior Statistician U S Public Health Service United States Treasury Department Public Health Service Public Health Bulletin No 207 Prepared by direction of the Surgeon General Paper Price 7 cents Pp 26 with 6 illustrations Washington D C Supt of Doc Government Printing Office 1933

The Health of Workers in Dusty Trades. General Statement and Summary of Findings. III Exposure to Dust in Coal Mining. IV Exposure to Dust in a Textile Plant. V Exposure to the Dust of a Silverware Manufacturing Plant. VI Exposure to Municipal Dust (Street Cleaners in New York City). From the Office of Industrial Hygiene and Sanitation United States Public Health Service United States Treasury Department Public Health Service Public Health Bulletin No 205 Prepared by direction of the Surgeon General Paper Price 7 cents Pp 37 Washington D C Supt of Doc Government Printing Office 1933

Mortality of Coal Miners By Dean K. Brundage Statistician Office of Industrial Hygiene and Sanitation United States Public Health Service United States Treasury Department Public Health Service Public Health Bulletin No 210 Prepared by direction of the Surgeon General Paper Price 5 cents Pp 17 Washington D C Supt of Doc Government Printing Office 1933

These three bulletins together with two others (numbers 176 and 187) constitute a series of studies dealing with exposure to the hazards of dusty occupational environments. They show that the mortality of coal miners from influenza and pneumonia is higher than that of the general population not only during epidemics but at other times. Mortality from respiratory tuberculosis was found to be definitely low among bituminous miners but not among anthracite miners. Deaths from all respiratory diseases are high among anthracite miners. The findings in America are similar to those among anthracite miners in Wales and to the findings among bituminous miners of England and Wales.

The study on dust in textile industries shows that dust is not important in this industry but that high temperature and humidity may be of importance although this study does not bring out any definite proof of excessive mortality due to these conditions. This confirms similar observations by English investigators.

The report on the health of workers in dust trades indicates that the usual division into dusty and nondusty trades has no great meaning, but, more specifically, one must know what is the quantity of dust in the air and what is its composition especially the percentage of free silica in the form of quartz. The results, sickness surveys, dust samplings, physical examinations and a limited number of roentgen studies are detailed.

These three reports deserve a place in the library of every physician who is interested in industrial hazards, especially those involving dust, high temperature and humidity.

Reports of the Committee Upon the Physiology of Vision. XI Individual Differences in Normal Colour Vision. A Survey of Recent Experimental Work (1910-31). By W. G. D. Fries. Medical Research Council Special Report Series No. 181. Paper. Price 2s. 1p. 96 with 22 illustrations. London: His Majesty's Stationery Office, 1932.

This is a survey of the experimental work between 1910 and 1931 and a review of the literature dealing with color vision, compiled by the author for the National Institute of Industrial Psychology. In consequence the bibliography is extensive comprising 101 references and seemingly complete. The material is divided into seven sections dealing with brilliance or luminosity discrimination, saturation discrimination, chromatic sensibility, differences in after excitation phenomena, differences in the color field, color anomalies and other color vision experiments. Conclusions cannot be arrived at in a work of this character, but the four definitions of terminology adopted by the American Optical Society and reprinted in the pamphlet may well be quoted here.

Color is defined as the general name for sensations arising from the activity of the retina and its attached nervous mechanism, this activity being in nearly every color normal individual a specific response to radiant energy of certain wavelengths and intensities.

Brilliance is that attribute of any color in respect to which it may be classed as equivalent to one member of a series of grays.

Hue is that attribute of certain colors in respect to which they differ from a gray of the same brilliance.

Saturation is that attribute of all colors possessing a hue which determines their degree of difference from a gray of the same brilliance.

This is essentially a reference pamphlet for all but those who are working in that special field, and it contains much valuable information.

Report to the United States Government on Tuberculosis with Some Therapeutic and Prophylactic Suggestions. By S. Adolphus Knopf, M.D. Revised and Enlarged Report Submitted to the State Department, War Department and War Veterans Bureau as Government Delegate to the International Union Against Tuberculosis Held at The Hague, Sept. 6-9, 1932. By S. Adolphus Knopf, M.D. Cloth. Price \$1.10. Pp. 59 with 51 illustrations. New York: National Tuberculosis Association, 1933.

This is a report to the United States government and specifically to the Secretary of State, the Surgeon General of the United States Army, and the Director of the War Veterans Bureau, of the author's experiences as official delegate to the eighth conference of the International Union Against Tuberculosis, held at The Hague in 1932. It deals with a discussion of gold therapy recommending that further experimentation be limited to an international committee which will conduct such experimentation under careful control. "We may thus obtain such reasonable certainty as is humanly possible as to the real value of this new and costly remedy. Until then, let the poor consumptives keep their gold in their pockets instead of having it injected into their veins."

The author describes the after-care of the tuberculous civilian and ex-soldier in Europe and the United States pointing out particularly the need for more rehabilitation institutions for the convalescent patient such as the New York Workshop for the care of the Jewish tuberculous in New York, the Tomahawk Lake Camp, operated by the state of Wisconsin, the Potts Memorial Hospital, and others. He includes chapters on massage, hydrotherapy, respiratory therapy and especially, diaphragmatic respiration, which the author himself first suggested. There is also a chapter on special exercises and one on skin tuberculosis, with particular reference to the salt-free diet. As a summing up of the present status of the tuberculosis problem this is a valuable monograph.

Diphtheria Immunization. Propaganda and Counter Propaganda. Compiled by J. Greenwood Wilson, M.D., MRCP, DPH. Preface by J. Graham Forbes, M.D., FRCP, DPH. Paper. Price 2/6. Pp. 111. Dewsbury, England: Joseph Ward & Company, 1933.

Dr. Wilson has faithfully recorded by reprinting all documents concerned, his controversy with the 'antis' over diphtheria immunization. His technique is not that of his opponents who reprint from medical literature only what serves the ends of their propaganda. His book proves that the antivaccinationists, the antivivisectionists and their like wherever they may be found, are like 'the Colonel's lady and Judy O'Grady sisters under their skins'. British or American, they go to the ends of the earth to find the few regrettable accidents that have occurred in connection with immunization and gloat over them. They display the same cynical disregard for accuracy in England as in the United States, even while using facts to malign truth. Dr. Wilson was attacked, and was compelled to defend himself, which he did with shrewdness, wit and a great deal more good humor than his adversaries, even after his personal motives had been impugned. One leaves the book with a depressing sense of the futility of argument with fanatics whose minds are dominated by their emotions and who are absolutely impervious to reason. In a difficult position Dr. Wilson, subjected to the needless additional disadvantage of having one of his friends support him anonymously and thus give the 'antis' fresh opportunities which they were not slow to use acquitted himself well. The book should be useful to his colleagues in public health work on both sides of the ocean, as well as of interest to practicing physicians. Especially pertinent is the remark made by Dr. Wilson that the private practitioner could have done the immunizing better and not have been subjected to such public baiting as was the medical officer of health. This is but another demonstration of the necessity for maintaining the personal relationship between patient and physician.

Atlas of Otology Illustrating the Normal and Pathological Anatomy of the Temporal Bone. By Albert A. Gray, M.D., F.R.S.E. Volume II. Cloth. Price 26s. Pp. 72 with 92 illustrations including 33 stereoscopic photographs. Glasgow: Jackson, Wylie & Company, 1933.

As the author states: "Since the first volume of this work was published eight years ago, the author has accumulated a considerable amount of new material which he hopes may justify the publication of the second volume. The material from which the illustrations for this second volume have been made has been obtained from both normal and pathological conditions, as was also the case in regard to the first volume." This atlas is a sumptuous and beautiful work consisting of ninety-two reproductions of illustrations of microscopic sections of various portions of the ear particularly the inner ear. A considerable number are stereoscopic. The first section of the book has twenty-four illustrations of normal anatomy, while the second section contains sixty-eight illustrations covering many phases of the pathologic anatomy. One may always be sure that any publication by Albert A. Gray will be most valuable, and the present work is no exception to that rule. It represents a stupendous amount of careful work, beautifully executed and exceedingly instructive. It is difficult to conceive how any more valuable atlas could possibly be devised. Its study by all who are interested in otology is highly recommended.

The Physical Mechanism of the Human Mind. By A. C. Douglas, M.B., Ch.B. Hon. Surgeon, Dunfermline and West Fife Hospital. Cloth. Price \$3.20. Pp. 241 with 24 illustrations. Baltimore: William Wood & Company, 1933.

The vast knowledge disclosed in the past few years in the field of neuro-anatomy and physiology would limit the utility of any work that tends to oversimplify the explanation of nervous phenomena. After criticizing psychology as a science, the author of this work takes a number of discrete facts from it and from physiology in an effort to show that the study of mind can be scientific—that expansion of the simple reflex arc with various neuron combinations explains how the mind works. Examples from simple biologic forms demonstrate the increase in complexity of behavior, and the author uses neurologic principles in the manner of elementary textbooks of physiology. When the author studies higher mechanisms than the stepping

reflex of the dog, he develops complicated explanations although still adhering to reflexology as his basic method. He illustrates his theory by means of diagrams designed to show the passage of the nervous impulse from the point of origin to the point of motor outlet, through reciprocal innervation, through the thalamic reflex system (omitting the "emotional" features of the basal ganglions), through cerebral reflexes, in an endeavor to explain gross bodily behavior and emotion. The later discussions depend on the concept of the conditioned reflex. The last part of the book is a combination of William James's psychology with some ideation drawn from the gestalt psychology, which results in explanations of thinking processes such as memory, thought, belief, reason, will and imagination, which do not fit the facts of modern comparative psychology. For example, he makes such statements as "Thought, or imagination, is merely inhibited action." The author does not refer to the experimental work done on animals, he is naive in his attitude toward inhibitory processes in the central nervous system, and he seems to know only the most popular work of Herrick and nothing of Morat, Lillie, Pike and many other experts in the field. The author states that the book will be useful for the nonspecialist, but his use of technical physiologic terms, philosophic concepts and neologisms makes it difficult for one to see exactly to what elementary student the book would be useful. Physiologists may find it an interesting attempt to simplify neurophysiology, but they and the psychologists will find the author's knowledge in their fields incomplete.

The Nervous Child at School By Hector Charles Cameron M.A. M.D. FRCP. Physician in Charge of the Children's Department, Guy's Hospital. Cloth. Price \$1.00. 1 p. 160. New York & London: Oxford University Press, 1933.

Many medical men are familiar with the author's previous works on nervous disorders of the nursery. As a sequel to this work he now offers the nervous disorders of the child at school. The author does not wish to emulate the serial narrative propensities of fiction writers but presents such advances in child psychiatry as have taken place since the last work was published. The author sets forth in simple language the common disorders that are manifested by the nervous child at school. Fatigue in school life and its attendant disturbances, the training in the home as a preliminary to school and the disorders of conduct that result from faulty adaptation are clearly presented. While the social conditions that surround children are different in England, the general facts are of interest both to the public and to the physicians of this country. This small book contains an interesting and lucid discussion of the problem of the nervous child at school and is highly recommended to the parent, teacher and physician who eventually share it.

Marie Stopes: Her Work and Play By Aylmer Maude. Authorized Edition. Cloth. Price \$3. 33 p. 299 with illustrations. New York: G. P. Putnam's Sons, 1933.

This is a biography by a disciple of an interesting woman with a mission. Dr. Stopes is a woman with an original, strong mind who worked in the biologic sciences. She became engrossed with the difficult problems of sex, particularly marriage, maternity and parenthood, and stepped into leadership in birth control with her book "Married Love." She is an engaging personality, and the book is an interesting and sympathetic account of her life as far as it has been lived for she is still an active worker. The later chapters of the book are given to the ups and downs of the birth control movement in recent years.

The Clinical Study and Treatment of Sick Children By John Thomson M.D. F.R.C.P. Fifth edition, written and enlarged by Leonard Hayday M.D. D.S. M.R.C.P. Physician, Princess Elizabeth of York Hospital for Children, London. Cloth. Price 30/- 1 p. 1075 with 344 illustrations. Edinburgh & London: Oliver & Boyd, 1933.

The fifth edition of the late Dr. John Thomson's textbook on "The Clinical Study and Treatment of Sick Children" has been prepared by Dr. Leonard Hayday. While the book has been extensively revised since the first edition eight years ago, the distinctive style of the text and the manner of presentation are essentially the same. Most of the revised data are concerned with the biochemical aspects of diseases as they occur in child-

hood, nutritional diseases, rheumatic fever and tuberculosis. The latter chapter is particularly up to date and comprehensive. However, such statements as "It can, we think, be laid down as a general law that pulmonary tuberculosis during childhood does not heal but is almost invariably fatal" and "pulmonary tuberculosis is preeminently a disease of infancy and early childhood" will hardly find general acceptance. Other statements are open to controversy but on the whole the author has succeeded in perpetuating a text that has enjoyed a considerable popularity. It is not recommended to those who are interested in a didactic discussion of diseases in childhood. The manner of presentation presumes a working knowledge of general medicine and will probably find its greatest usefulness in the hands of the practitioner of medicine. The illustrations are adequate and well done.

History and Source Book of Orthopaedic Surgery By Edgar W. Bick M.A. M.D. Adjunct Orthopaedic Surgeon, Hospital for Joint Diseases, New York City. Cloth. Pp. 254 with illustrations. New York: The Hospital for Joint Diseases, 1933.

The author presents in one volume a history of orthopedic surgery from ancient times up to the present. In his introduction he states that the book makes one realize to what a remarkable degree the men of former times, with their meager physical equipment, developed their skill in the absence of modern technique. The important points of each subject are put in the form of a historical summary. The book might be considered a companion volume to Sir Arthur Keith's *Menders of the Maimed*. Unfortunately, it is printed in typewritten form and closely spaced. It is this type of book which confirms the statement that the new in medicine is the old that has been forgotten.

Medicolegal

Workmen's Compensation Acts: Compensability of Poison Oak Poisoning—In the course of his employment, a workman came into contact with poison oak. Dermatitis venenata followed and he was disabled for about nineteen days. The Oregon industrial accident commission contended that the claimant's disease was idiopathic, not traumatic, and that it therefore was not compensable. The commission was guided apparently by an excerpt from *Corpus Juris*, an exact citation to which is not given in the reported case, reading, in part, as follows:

An idiopathic disease in the sense in which the term is used in the discussion of the cases arising in this connection is one which develops gradually or at least imperceptibly and while it may be attributable to external conditions is also dependent in part on conditions inherent in the individual.

The evidence, said the Supreme Court of Oregon, shows that contact with poison oak or poison ivy by persons susceptible to poisoning by them causes the disease known as dermatitis venenata, in one or two days after contact. The disease is attributable to external conditions. It is not dependent on conditions inherent in the individual, except that some persons are not susceptible to it. It therefore does not fall within the definition of an idiopathic disease in the sense in which that term is used in *Corpus Juris*, as a disease not compensable under the statute.

To recover compensation under the workmen's compensation act, said the Supreme Court, an employee must have sustained by accident arising out of and in the course of his employment, personal injury caused by violent or external means and causing disability. In the present case, the disease was not an occupational disease in the sense that it was the natural and unavoidable result of the employment. The claimant's contact with the poison oak brush happened by chance, he was in ignorance of its character, the contact was involuntary and unintentional on his part, and the result was unexpected. The contact arose out of and in the course of his employment and resulted in his disability. It was not an accident caused by violence, but it was caused by external means.

It has been held that disability resulting to a workman from contact with poison ivy is compensable under workmen's com-

pensation acts *Dent v. Railway Mail Ass'n* (C. C.) 183 F. 840, *Railway Mail Ass'n v. Dent* (C. C. A.) 213 F. 981, L. R. A. 1915A, 314, *Plass v. Central New England R. Co.*, 169 App. Div. 826, 155 N. Y. S. 854, *Sharon v. Town of Boonville*, 32 State Dept. Rep. (N. Y.) 545. The effect of poisoning from poison oak and poison ivy on the human skin and the disease condition resulting from them are shown to be identical. A workman is as much entitled to compensation in the one instance as in the other. The award of compensation was accordingly affirmed—*Baustier v. State Industrial Accident Commission of Oregon* (Ore.), 19 P. (2d) 403.

Construction of a Constitutional Medical Practice Act by State Court Binding on Federal Court Cults Need Not Be Named in Act—Certain chiropractors not licensed to practice in Pennsylvania filed a bill in the United States district court to restrain the Pennsylvania bureau of medical education and licensure from enforcing against them the penalties of the medical practice act unless and until the laws of the state provided specifically for the regulating and governing of the practice of chiropractic. They alleged that chiropractic is a healing art distinct from other healing professions, that the medical practice act provides for the licensing of practitioners of medicine and surgery, that the courts of Pennsylvania construe the medical practice act as embracing chiropractic, although there is no provision in the act whereby chiropractors may obtain licenses to practice their calling, and that by being required to obtain licenses "when in fact such a license cannot be obtained" their privileges and immunities as citizens of the United States had been abridged and they had been denied the equal protection of the laws and deprived of their property without due process of law, in violation of the fourteenth amendment of the United States constitution. The United States district court sustained a demurrer by the licensing bureau, and the chiropractors appealed to the United States circuit court of appeals, third circuit. They admitted, apparently, that the medical practice act construed as they would have it construed, was constitutional but they argued that as construed by the Supreme Court of Pennsylvania it was unconstitutional.

This bill, said the United States circuit court of appeals, presents something of a paradox in jurisprudence. While expressly disclaiming an attack on the constitutionality of the medical practice act, it seeks relief in a federal tribunal from the construction which the state courts have placed on the act, on the theory that the construction they have placed on the act is in contravention of the constitution. A federal court may restrain a state agency from enforcing an unconstitutional state statute, but it has no power to restrain the enforcement of a constitutional statute in the way in which the highest courts of the state have construed it. The circuit court of appeals held, therefore, that it was without power to grant the relief sought by the chiropractors.

The court, however, because of the earnest presentation of the case for the chiropractors, undertook to discuss and decide the question raised by them. The medical practice act of Pennsylvania, said the court, relates to the art of relieving and curing human ills commonly referred to as the "healing art." Of that art, the chiropractors admit themselves to be practitioners. The "healing art" is a generic expression and ordinarily embraces the entire art of healing and its many theories and practices. It falls clearly under the police power of the state. A state may exercise its police power by a system of regulation and control, which, if not unreasonable and arbitrary, is lawful and is binding on every one in the state. To assure its citizens skilled treatment of their ills by qualified practitioners, and particularly to guard them against malpractice by ignorant and unskilful practitioners, the state, acting within its police power, provided a general system for completely regulating the healing art, referring to it as the practice of medicine

and surgery." That a state may thus regulate the practice of medicine, using this word in its most general sense, can no longer be questioned.

It cannot be successfully asserted that the state was arbitrary or unreasonable in requiring that all who deal with the human body, diagnose its ills, and offer their services to the public, shall have the qualifications which the state by this act requires of them. The chiropractors in this case complain that the practice of chiropractic, though a healing art, has nothing in common with drugs, medicine or surgery, and that it is not "the practice of medicine and surgery," as the healing art is defined by the act. They claim that there is no law in respect to their branch of the healing art and that they may therefore lawfully practice their calling without licenses from the bureau of medical education and licensure and without subjecting themselves to criminal prosecutions. But, said the circuit court of appeals, the Pennsylvania courts have declared that the words practice of medicine and surgery "are taken in their most comprehensive sense whether with the aid of drugs or by any other remedial agencies whatever," and squarely hold that the practice of chiropractic, though not named therein, is comprehended in the expression "practice of medicine and surgery." When the highest court of a state construes a state statute enacted under the state's police power, the statute means what the court says it means. The construction by the court becomes a part of the statute, and the statute speaks as the court has construed it. The scope and effect of such a law, as distinguished from its constitutionality, are state questions, as to which the decisions of the state court of last resort are controlling. They are binding on all federal courts in which such construction is involved, whether they agree with it or not.

Accordingly, the decree of the district court dismissing the chiropractors' bill was affirmed—*Steinbach v. Metzger* (C. C. 1) 63 F. (2d) 74.

Medical Practice Acts Discretion of Jury in Revoking Physician's License—The Georgia medical practice act (Park's Code Supp. 1922, Sec. 1697[m]) provides that, if a licensee has been convicted of a crime involving moral turpitude, the board of medical examiners may revoke his license. A licensee whose license has been revoked may appeal to the appropriate superior court, which will try the cause de novo. Under the statute, said the court of appeals of Georgia, division No. 2, the exercise of the board's power to revoke a license is discretionary with the board. When a license has been revoked, an appeal to the superior court is a new proceeding and it is discretionary with the jury whether or not to revoke the appellant physician's license. In a hearing on such an appeal, therefore, it is error for the court to instruct the jury to revoke a physician's license. In the present case, the physician had been convicted of making a false certificate of death in a claim filed under a life insurance policy, a crime involving moral turpitude. The board revoked his license, and he appealed to the superior court Floyd County, where the cause was tried de novo. The trial court excluded evidence in mitigation of the charge, which tended also to establish the appellant's innocence. This was error, said the court of appeals. Such evidence was competent and relevant to the issue and might have influenced the jury in the exercise of its discretionary power to revoke the defendant's license—*Smith v. State Board of Medical Examiners* (Ga.) 167 S. E. 769.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Studies of Retinopathies I Diabetes Mellitus E B Gresser New York—p 612

Retinopathies and Diabetes Mellitus—In a study of 100 cases of diabetes mellitus Gresser correlates the clinical signs of hypertension, retinal vascular sclerosis and abnormal urinary elements, together with age and duration of the disease state. The cases are divided into three general classes: group 1, retinal pathologic conditions; group 2, sclerosis of the retinal vessels; and group 3, cases without discernible changes in the vessels or retinal elements. Of group 1, 38 per cent presented a retinopathy in which sclerosis and hypertensive signs in the vessels were almost uniformly present. Associated nephritic lesions appeared in 23.5 per cent of which 10.2 per cent were classed as chronic diffuse glomerular nephritis and 7.7 per cent referred to renal changes in nephrosclerosis. Of group 1, 7.2 per cent were noted as having benign hypertension. The average age for this group was 55.13 years and the diabetic state averaged 7.34 years. The retinopathy seen in these diabetic patients did not conform to one clear picture; no entity having been established. The majority showed characteristics of hypertensive retinitis both vascular and exudative. No relationship was seen between the presence of retinopathy and the severity of diabetes. Signs of retinal vascular sclerosis without other vascular or retinal changes were present in 30 per cent. All of these (group 2) were free from renal disease and permanent hyperopia was absent. The average age in this group was 55.3 years and the duration of the diabetic state was 5.77 years. It was apparent that the duration of the diabetic state was not a direct factor in the production of retinal pathologic changes. Group 3 showed no alterations in the retinal vessels or tissues. Blood pressure ranges were entirely normal and the urinary pictures always negative (sugar excepted). The average age was 31.1 years and the duration of diabetes was 4.5 years.

Sarcomatoid Metastases in Lymph Nodes Draining Primary Carcinoma with Sarcomatoid Stroma R B Greenblatt, Montreal Canada—p 525

Neuroblastoma Metastases in Bones—Colville and Willis describe a case in which a tumor presenting all the accepted characteristics of Ewing's sarcoma of the bone was shown at necropsy to be one of many metastases from a suprarenal neuroblastoma. A review of certain adequately recorded necropsy cases of supposed multiple bone sarcomas leads to the conclusion that these also were instances of suprarenal neuroblastoma with skeletal metastases. The term "Ewing's sarcoma," while possessing clinical value as defining a syndrome presented by a certain group of tumors affecting bones, has no established claim as designating a pathologic entity. While not denying the possible existence of a primary bone tumor presenting the Ewing syndrome, the authors believe that further study will disclose the metastatic nature of most of the tumors with this syndrome, and they strongly suspect that suprarenal neuroblastomas will prove to be the primary growths in many of the cases.

Types of Cells in Hypophysis in Women—Rasmussen determined the relative number of chromophobes, acidophils and basophils in the anterior lobe of the hypophysis of ninety-four carefully selected and supposedly normal, formaldehyde-fixed hypophyses of nonpregnant women from 16 to 84 years of age from cases of sudden or accidental death, and of twenty-five pregnant women from 15 to 39 years of age. The data were obtained by counting all the cells containing nuclei in an average of 214 equally spaced microscopic fields from three different, well separated sections 5 microns in thickness from each hypophysis and by using Mallory's connective tissue stain after slight staining with hematoxylin to bring out the nucleus. In the group of nonpregnant women the chromophobes average between 49 and 50 per cent of all the cells with a coefficient of variation of 14, the acidophils average between 43 and 44 per cent, with a coefficient of variation of 19 and the basophils average 7 per cent, with a coefficient of variation of 42. These figures are radically different from those given for a mixed group of women and a group of female dementia praecox cases by McCartney, in both of which he reports three times as many basophils and only half as many chromophobes. Women more than 50 years of age show an average of 4 per cent more chromophobes, nearly 2 per cent more basophils and 6 per cent fewer acidophils than those below 50 years of age. There is no correlation between body length and any particular type of cell. While there are on an average relatively fewer acidophils and more chromophobes in the pregnant women than in the nonpregnant the differences are too small to be statistically significant. Contrary to the opinion of many, the enlargement of the anterior lobe of the hypophysis during pregnancy is apparently not due to marked hyperplasia of any one of the three generally recognized types of cells nor could a special so-called pregnancy cell be identified. Women have a distinctly higher proportion of acidophils than men, and men have a higher percentage of chromophobes and basophils.

Calcified Epithelioma of Skin—Chiu reports ten cases of calcified epithelioma of the skin examined in the pathologic laboratory of the Peiping Union Medical College. These tumors form a distinct group of neoplasms that are anatomically and clinically well defined. They are circumscribed, well encapsulated growths beneath the skin consisting of lobulated epithelial masses with a network of usually hyalinized fibrous stroma. The epithelial cells are small, oval, deeply staining and closely packed and have a marked tendency to undergo necrosis, calcification and ossification. The author's study of his ten cases and the 116 cases that he collected from the literature indicate that they are distributed most frequently on the head and neck and occur usually among younger persons. The majority of these tumors are benign but a few cases of recurrence following removal have been recorded.

Nonopaque Foreign Bodies in the Bronchial Tree—

Pendergrass states that among the conditions with which bronchial obstruction due to nonopaque foreign bodies may be clinically confused are acute or unresolved pneumonia, lung abscess, asthmatic obstructive atelectasis, massive tuberculosis, atelectasis due to extrinsic pressure by enlarged tracheobronchial glands or tumors, benign or malignant intrabronchial tumors, congenital bronchial stricture, and laryngeal diphtheria. A roentgen study of suspected cases is always indicated and often proves diagnostic, although bronchoscopic confirmation is needed. No patient should be submitted to bronchoscopy without roentgenologic examination. The roentgenologic examination should consist of roentgenoscopy and of roentgenograms made in inspiration and expiration. Lateral views of the thorax are of value in determining what lobes are involved. Bronchography with iodized oil would demonstrate bronchial obstruction, but its application in children, in whom the majority of the cases of foreign body through aspiration occur is often difficult. If

this procedure is employed in a child in a suspected case of bronchial occlusion by a foreign body, the transcricoid route should be used, as attempts to introduce oil between the vocal cords by means of a catheter might so traumatize the cords as to produce edema, a condition unfavorable to the eventual bronchoscopy that must be done to remove the foreign body. The possible presence of a foreign body in the tracheobronchial tree should always be borne in mind in considering pulmonary disease in children.

Physiologic Responses to Temperature—Talbott and his associates present observations which they believe permit the following conclusions as to the mechanism of adaptation to high climatic temperatures. 1 There is a loss of body weight in the first days after going to such an environment. 2 The fluid intake is greatly increased and closely related to the elevation of the temperature. 3 The volume of urine under goes little change, but the specific gravity increases to 1.03 or 1.035. This returns to 1.015 or 1.02 after the period of adaptation. 4 The twenty-four hour excretion of nitrogen in the urine is less than in temperate climates. A lowered protein intake is partially responsible for this effect. 5 The amount of sodium chloride lost in the sweat is greater in the first days after going to a high climatic temperature. This is accompanied by a diminished excretion of chloride in the urine. When adjustment is effective, the salt concentration in the sweat decreases and the amount of chloride in the urine increases. 6 The changes from normal in the constituents of the blood are small, when adaptation has been satisfactory.

Hydrocinchonidine and Hydrocinchonine in Malaria

—In view of the previous use of hydrocinchonine by Giemsa and Werner in doses up to about 0.8 Gm of alkaloid daily, Stone and his associates considered that 0.5 Gm of the alkaloid, which is practically anhydrous, or 0.65 Gm of the sulphate once daily, should not be dangerous. So far as they could find hydrocinchonidine had not been used in therapeutics previously. A dose of 0.5 Gm of hydrocinchonidine alkaloid dissolved in acetic acid, was well tolerated by one of the authors. It was therefore considered that a single daily oral dose of 0.5 Gm should be safe. The drugs were given by mouth, usually in capsules and in most cases a few hours before the ordinary hour of the paroxysm in the particular case. The diagnosis of malaria was confirmed in all cases by examination of the peripheral blood. Of the five patients who were given hydrocinchonidine all received the drug in capsules, about 0.5 Gm once daily for four days. Four had the benign tertian infection and one the estivo autumnal, the symptoms disappeared in all cases and the parasites in three with benign tertian infection. Hydrocinchonine treatment was attempted in eleven cases. Two patients were given six days of treatment for benign tertian relapse; the response was slow but the fever was terminated and blood smears became negative in both cases. Six patients were each given four days only of treatment, one of these vomited shortly after the first dose but completed the course of treatment without further difficulty, four of these patients had benign tertian infection and two estivo autumnal, paroxysms ceased in all cases and the blood smear became negative in four, including one of the estivo autumnal cases. Of the three patients with benign tertian infection who failed to complete four days of treatment, one became nauseated and the other two vomited, but one of the latter also vomited quinine that was given later and in the one who was nauseated a quotidian fever disappeared after the first dose.

Ultra-High Frequency Pyretotherapy of Neurosyphilis—Simpson and his associates submitted 100 patients with syphilis, arthritis, gonococcal infections or vascular diseases of the extremities to 5,000 hours of sustained fever therapy without evidence of injury, except for superficial skin burns in some of the patients treated before the development of the air-conditioned cabinet. With due regard to the relatively short time during which their patients have been under observation, the authors state that the results obtained with combined antisyphilitic therapy and radiotherm pyretotherapy in cases of neurosyphilis are at least comparable to the results obtained with the more hazardous regimen of malaria and antisyphilitic therapy. The fact that the most brilliant results are achieved in cases of early neurosyphilis, together with the remarkable observations of Kyrle in the treatment of early syphilis with the more hazardous unreliable and time-consuming regimen of malaria and antisyphilitic therapy make it probable that the logical time to institute combined fever and antisyphilitic therapy is immediately following the establishment of the diagnosis of syphilis.

Renal Insufficiency Following Blood Transfusion—VonDeesten and Cosgrove report a case of renal insufficiency in which recovery followed the transfusion of 750 cc of blood and seemed to depend on venesection. An immediate reaction occurred which was evidenced by a sharp rise in temperature accompanied by hematuria hemoglobinuria and oliguria. A delayed reaction occurred, which reached its peak on the ninth day. This reaction was characterized by severe uric symptoms headache, rigidity of the neck, convulsions and coma. Repeated blood examinations during this period showed marked retention of urea nitrogen and creatinine. Venesection of 450 cc of blood, followed by the introduction of 500 cc of physiologic solution of sodium chloride intravenously, resulted in an immediate cessation of the uric symptoms.

Tumors of Third Ventricle—Zimmerman and German present two instances of colloid cyst of the third ventricle, with their detailed clinical histories and anatomic observations, and tabulate twenty-eight similar cases from the literature, with a summary of the clinical features and essential pathologic observations in each. They call attention to certain symptoms of diagnostic aid in the localization of the lesion and lay emphasis on the localizing value of ventriculography, which procedure was eminently successful in both of their personal cases. They conclude that these cysts are usually derived from the choroid plexus of the third ventricle but concede the possibility that in certain instances they may be derived from the ependyma lining this cavity. It also appears possible that rarely such a tumor may be derived from a persistent paraphysis.

Thrombosis of Intracranial Arteries—Hyland gives the histories and pathology observed in three cases of cerebral thrombosis, illustrating the syndromes associated with softening in the distribution of the anterior cerebral, basilar and internal carotid arteries, respectively. One of the patients, a woman aged 61, collapsed while working. She experienced no loss of consciousness but was unable to stand. Three days later, she complained of weakness in the left arm. Fresh hemorrhages were present in the right retina. The left arm and leg lay immobile in extension, the left leg was completely paralyzed, the left arm was partially paralyzed, with apraxia and a grasp reflex present. The right arm and leg were in a constant state of motor activity, the right hand grasping objects within reach but releasing them on command. A few days later she became aphasic, the right arm and leg were totally paralyzed, the left arm, formerly immobile, moved, constantly groping at objects. There was some return of power in the left leg. Both plantar reflexes were in extension. Subsequently the patient became comatose, and all movement in the limbs ceased. Death occurred on the twelfth day after the onset. At post-mortem examination an anomalous distribution of the anterior cerebral arteries was found. They joined to form one long stem which subsequently divided into two on the dorsum of the corpus callosum. A thrombus was present in the common trunk. Another patient, a man, aged 42, previously well except for frequent head colds and postnasal discharge suddenly had a severe headache, followed shortly by a left hemiplegia and transitory diplopia. Examination was negative except for slight residual signs of hemiplegia and right quadrantic homonymous hemianopia. The Wassermann test of the blood was positive and the cerebrospinal fluid showed a positive Kahn reaction but was otherwise not abnormal. There was glycosuria which was of intracranial origin. Two weeks after admission there developed divergent strabismus, dysarthria, nystagmus and weakness of the left leg. These symptoms tended to improve but three days later convergent strabismus, left facial weakness and right hemiparesis developed. The pupils were very small. Death occurred suddenly from respiratory and cardiac failure. Post-mortem examination showed thrombosis of the basilar and left vertebral arteries, advanced cerebral arteriosclerosis and acute sphenoidal sinusitis. No evidence of syphilitic disease was found. The other patient a man aged 58 under dietary treatment for a mild diabetic condition, while convalescing from pneumonia suddenly had paralysis of the left arm and leg. Six hours later, he was semicomatose, the right pupil failed to react to light, severe left hemiplegia was present, involving the face arm and leg and sensory impairment was present over the paralyzed area in the face and left arm. Examination on the third day showed blindness in the right eye. Ophthalmoscopic examination indicated that thrombosis of the central artery of the retina was the cause. The left hemiplegia had improved particularly in the leg. During the following week he became increasingly comatose and signs of extensive pulmonary involvement appeared. He died on the tenth day after the onset of the hemiplegia. A post-mortem

examination showed that the right internal carotid artery was occluded by a thrombus and, likewise, the right middle cerebral artery as it lay in the sylvian fissure. There was a large area of softening in the distribution of the right middle cerebral artery. The cerebral arteries showed only moderate degenerative changes in their walls.

Toxic Gout.—Brain states that toxic adenoma is a non-neoplastic condition requiring nonsurgical treatment. In its treatment roentgen therapy, in combination with rest, dietary and other medical means, relieves the toxicity and prepares the patient for a relatively riskless thyroidectomy. In the management of exophthalmic goiter, roentgen treatment is a valuable supplement to careful medical management and may abbreviate the period of invalidism. Inexpert roentgen therapy may result in a dangerous crisis or in the total elimination of the thyroid function. The prognosis of exophthalmic goiter under proper nonoperative treatment is excellent. Statistics of the author's series of 2,000 patients so treated and followed up for a period of from three to ten years indicate perfect recovery in more than 90 per cent.

Operations in Cerebellar Medulloblastomas.—Elsberg and Gotten state that the lower operative mortality rate of their twenty-three patients with cerebellar medulloblastomas in whom a simple suboccipital decompressive operation was

performed and the fact that in these patients the average survival period was about as long as that after more radical tumor extirpations are weighty arguments in favor of conservative surgical intervention. A comparison of the results in their series with those in which primary radical removal of the tumors is usually attempted justifies the conclusion that, at the first operation, the best result will be obtained if the procedure is limited to a liberal suboccipital decompression with the removal of only sufficient tissue for histologic verification, followed by thorough roentgen treatment. There is some evidence to support the belief that, if the primary operation was limited to a decompressive craniotomy and the attempt at radical removal was made at a later time when the patient was no longer acutely ill, after the increase of intracranial pressure had subsided and after the patient had received a series of roentgen treatments, the operative mortality would be reduced. The average survival period of the patients who recovered from one or more operations was 173 months. Of the ten patients in whom only conservative operations were performed it was 175 months, while in the patients in whom a more radical procedure was done primarily or secondarily after a conservative procedure and who recovered from the operation the average total survival period was 165 months. Of the entire series two patients are living one, twenty-one months after a conservative operation, and the other, forty months after a conservative operation followed by a more radical operation. The mortality after conservative operations was 13 per cent.

Excretion of Theelin and Prolan in Migraine.—Riley and his associates made daily hormone studies over a prolonged period on the urine of thirteen patients, eleven women and two men suffering from migraine. In each instance the period of observation included a typical attack. In the women, these studies embraced the quantitative estimation of female sex hormone and the identification of prolan. In men, only the prolan identification was included. No distinction was made between prolan A and prolan B. In the women, female sex hormone was usually absent or present in much reduced quantities. A total of twenty-nine headaches occurred in the women during the period of observation. Twenty of the headaches were preceded in their onset by the appearance of prolan in the urine. Of the remainder, the test could not be adequately conducted in seven, in the other two, proper specimens were available but the headache occurred without the antecedent appearance of prolan. In one of the two men a prolan headache relationship was demonstrated, this was not always present in the other. The injection of follutein resulted in the appearance of a characteristic attack of migraine in seven of nine women. The results would indicate that the presence of prolan in the urine is definitely related to the occurrence of the migrainous seizure. Substantiation is given to the hypothesis that ovarian and presumably hypophyseal activities are closely related to the occurrence of migraine. The results of the present studies suggest that this mechanism is one of hypophyseal hyperfunction or of ovarian hypofunction and that prolan itself plays an important part. The occasional demonstration of prolan or the injection of follutein without the subsequent development of symptoms, as well as the interval between the spontaneous first appearance of prolan and the commencement of symptoms, suggests that an additional, unknown factor is involved in the production of the migrainous seizure. The mechanism by which prolan acts is at present unknown. Prolan may appear in the urine of men.

Dangers of Ventriculography.—From the study of the literature and from his own experiences, Riggs concludes that fatalities after ventriculography are rarely due to hemorrhage into the ventricles but to the profound effects of the removal of fluid and the introduction of air on the pressure conditions within the cranial cavity. In 148 ventriculographies there were twelve deaths. Most of the fatalities occurred in patients with advanced symptoms and signs of intracranial tumor. Dangerous symptoms often occurred when the growth was subcortical and so situated as to make pressure on the third ventricle and the brain stem. Dangerous symptoms followed by recovery occurred in thirty-one patients, and in twenty-three of these the growths were deeply situated beneath the cortex. Caffeine and hypertonic solution of dextrose given intravenously were

rarely of benefit. The frequency of the occurrence of pressure conditions is not proportionate to the degree of dilatation of the ventricles or the amount of increase of intracranial pressure. Puncture of the ventricle and release of the air will often relieve the symptoms. Ventriculography is a valuable and indispensable diagnostic procedure. It should be used only in those patients in whom localization of the tumor is impossible by clinical means or in whom serious doubt exists regarding the correctness of the clinical localization. Caution is indicated when a supratentorial growth is causing pressure on the third ventricle or the brain stem.

Water or Fat—Rowntree and Brunsting describe the cases of two women 20 years of age, who presented endocrine obesity of rapid onset. Menstruation and puberty in both instances started three or four years prematurely, followed by rapid, inexplicable and marked obesity developing between the ages of 18 and 20 and resisting all forms of antiobesity management. On physical examination, both patients were seen to be superlatively feminine in appearance with luxuriant hair and exaggerated feminine configuration. One patient had menstruated at two-week intervals and presented also urticarial lesions and angioneurotic edema. Proceeding on the basis of deranged water metabolism these patients were subjected to dehydration through the use of ammonium salts and the newer mercurial compounds resulting in the reduction of their weight to practically normal. On returning home, the weight was regained in one patient but fully controlled in the other through the use of ammonium and mercurial compounds and water

restriction. It was thought that this syndrome might be explained on the basis of an early excess of prolactin A resulting in early puberty and a subsequent excess of pituitrin resulting in water retention. The syndrome may be regarded as the antithesis of diabetes insipidus.

Gastro-Intestinal Disturbances and the Endocrinopathies—Friedenwald and Morrison point out that the endocrinopathies play an important part in the production of digestive disturbances. The glands chiefly concerned are the thyroid, parathyroids, pituitary and suprarenals. Hyperthyroidism gives rise to diarrhea and increased metabolism and digestive symptoms, which can often be held in check by the use of compound solution of iodine together with proper hygienic measures. When these procedures fail, thyroidectomy is indicated. Hypothyroidism is associated with constipation and decreased metabolism, and these, in addition to other symptoms, can be controlled by the use of thyroid extract or thyroxine. Parathyroid deficiency is closely related to disturbances of calcium excretion, and tetany is observed in gastroduodenal dilatation and upper intestinal obstruction. Calcium salts and parathyroid extract (parathormone) are indicated in these conditions, and salt solution and dextrose when dilatation occurs with alkalosis. Disturbances of the pituitary gland give rise to obesity, enlargement of the abdominal organs and increased thirst associated with diabetes insipidus. Solution of pituitary restores tone and may overcome functional intestinal obstruction, distention of the intestine and constipation. The suprarenals inhibit peristalsis, and the relation of peptic ulcer to suprarenal dysfunction is emphasized. In Addison's disease in which the cortex is involved, marked gastro intestinal symptoms are produced. Epinephrine has been found of value in relieving visceral spasm and cortin in the treatment of Addison's disease. It has been definitely established that a functional relationship exists between various endocrine glands and that a dysfunction in one frequently develops a change in function in another, so that the cause of the production of gastro-intestinal symptoms is at times difficult to discover.

Diarrhea in Children—Reglien treated twelve cases of diarrhea with the apple diet. The diarrheas were due to various causes. The ages ranged from 6 months to 9 years. Four cases were of the usual "summer diarrhea" type. In three the diarrhea followed upper respiratory infections, and two were convalescent from measles. One case was that of a baby aged 18 months, with furunculosis, and another, a girl of 4 years, had diarrhea following a dietary indiscretion. The diet given by the author is that of Moro with a modification in the use of drugs. Ripe, freshly grated or scraped raw apples are used. The apples should not be overripe, and none of the seeds, skin or core are used. The apples are prepared only as used. In the treatment of the less severe cases on the first and second days from 100 to 200 Gm of grated raw apple is given from four to five times a day. One day is usually sufficient, although in severe cases it may be necessary to use the apples for two days. As other foods are added, the apples are continued in decreasing amounts. Calcium carbonate, from 5 to 10 grains (0.32 to 0.65 Gm), and phenobarbital, from $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.016 to 0.032 Gm), are given three times a day throughout the first week of treatment. With infants and older children, the calcium carbonate may be mixed with the apples. If necessary, glucose may be added to sweeten the grated apples. On the third day, cottage cheese, dry toast oatmeal gruel with the white of one egg and tea are

added, on the fourth day, two egg yolks and some mashed potatoes, on the fifth day, butter, and on the sixth day, meat. Skimmed milk may be used on the fifth or sixth days in the mild cases.

Vasomotor Rhinitis—Sprucke applied pure phenol to the nasal mucous membrane in sixteen patients with vasomotor rhinitis, some of them complicated with asthma, hay fever and chronic sinusitis, who had obtained little or no relief from various other treatments. Phenol, when applied to the mucous membrane of the nose, blocks the nerve endings in the mucosa but does not induce desensitization. The application is accompanied by little or no pain. The after effects, which on the average last about two days, are headache, nasal obstruction, a grippy feeling and pain in the nose. Two patients had occasional nose bleeds. Phenol leaves no scars nor is there any impairment to the sense of smell. Of the sixteen patients with vasomotor rhinitis so treated ten had complete and almost immediate relief and three were moderately relieved. Of the four patients whose cases were complicated by pollen asthma, three were relieved of their asthmatic symptoms. The two patients with asthmatic bronchitis and three with vasomotor rhinitis were not relieved. The application of pure phenol to the nares relieves rhinorrhea, sneezing and nasal obstruction in vasomotor rhinitis. The permanence of this relief is as yet uncertain. All the patients are still under observation.

Titration of Yellow Fever Virus—Davis and his associates made titrations of yellow fever virus in stegomyia mosquitoes, using rhesus monkeys as test animals. They found

that 1 The average mosquito immediately after engorging on highly infectious blood contained between 1 and 2 million lethal doses of virus. The titer of freshly ingested blood was as high as 1 billion lethal doses of virus per cubic centimeter. 2 During the fortnight succeeding a meal on infectious blood there occurred a reduction of titratable virus to not more than 1 per cent of that present in the freshly fed insects. 3 The titer was somewhat higher at later periods. This rise in titer signified possibly not a multiplication but merely an increase of extracellular virus and of that easily freed by grinding to a titratable form. 4 At no later stage did the quantity of titratable virus equal that demonstrated in freshly fed insects.

Antipneumococcal Humoral Immunity—Graesser and Harrison tested fifty-five persons to determine the pneumococcal promoting activity of their serum against pneumococci types I and II. By repeated tests an attempt was made to study the constancy of the degree of their immunity over intervals of from two to six months. In this group were included nine persons with common colds and twelve cases of a severe influenza-like infection. Fifteen of the fifty-five persons showed a change in the titer of their humoral immunity against either type I or II or both. Three of these showed an increase, and two a decrease. This reaction in most instances was a specific one in that the altered reaction toward one type was not associated with a similar change toward the other type of pneumococcus. Colds and influenza-like infections apparently exerted no effect on the titer of humoral immune substances.

Mechanism of Focal Infection—Kau recovered streptococci and staphylococci from presumably primary foci in twenty-one cases of chronic focal infections. Sterile filtrates of broth cultures and young whole cultures were injected intravenously into rabbits. The lesions produced by the two were frequently similar in degree and distribution. Synovial and pericardial

changes were most frequently produced. There was no evidence of elective or selective localization on the part of either filtrates or whole organisms in the rabbits of either series. It would appear that toxins produced in the primary foci of focal infection may be absorbed and produce the secondary lesions. The author suggests that the early secondary lesions of focal infection may be due to these toxins and that the drainage or extirpation of primary foci may afford prompt therapeutic results. In long established chronic secondary infections however, the organisms themselves may be productive of the lesions and therefore probably independent of the primary foci and account for the absence of therapeutic improvement following their drainage or extirpation.

Bismuth in Treatment of Syphilis—Beckman states that the water soluble bismuth salts are rapidly and fairly regularly absorbed but usually cause pain on injection. The only suspensions are more slowly absorbed than the aqueous solutions and may cause embolism or infarction or be followed by troublesome abscesses but they need be injected only once a week and the injections are not usually painful. Only the use of individual ampule preparations insures reliable dosage. The absorption of the liposoluble preparations begins almost as quickly as that of the aqueous solutions but proceeds more nearly at the slower rate of the oily suspensions. The injections are relatively painless and rarely leave sequelae, they must, however, be made as frequently as when using aqueous solutions. In early syphilis bismuth can apparently satisfactorily replace mercury but should not be employed exclusively until statistical studies have proved its superiority beyond doubt. In late syphilis, there seems to be no doubt that bismuth, properly used with mercury and the iodides often makes the use of the arsphenamines unnecessary, a negative Wassermann reaction is sometimes accomplished in stubborn latent cases. In neurosyphilis, bismuth has proved its right to be added to the list of effective agents but not to usurp the place of any of the others. In congenital syphilis, when used alone bismuth is of greater value than mercury alone but probably less valuable than the arsphenamines. It sometimes gives a negative Wassermann reaction when the other two drugs have failed. In syphilis intolerant to arsenic, bismuth is of value as an alternate drug with mercury. The toxicity of bismuth is much lower than that of either the arsphenamines or mercury.

Effect of Blood Transfusion on the Heart—Polaves and his associates observed that it is not always safe to perform a blood transfusion on a person known to be suffering from cardiac or cardiovascular disease. In the performance of about 3,500 transfusions one of the authors noticed a number of reactions which seemed to be due to cardiac embarrassment all other known causes having been excluded. In no instance could the reaction be ascribed to incompatible blood or other demonstrable cause. Since there was evidence of existing cardiac pathologic changes various experiments were undertaken to study the effects of transfusion, in order to determine if possible the part played by the heart in these reactions. Electrocardiographic observations made before during and after blood transfusions of patients with normal and diseased hearts throw little light on the changes in the heart during blood transfusion even though there is definite clinical as well as electrocardiographic evidence of existing heart disease. In one case there were definite anginal symptoms during the transfusion with no changes in the electrocardiographic tracing. Other means than the electrocardiograph must be sought as an aid to determine the effects of transfusion on a diseased cardiovascular system.

Intracarotid Treatment of Meningitis—Ersner and Myers believe that their technic will minimize the extravascular and intravascular changes, especially thrombosis of the vessel, atheromatous changes and aneurysm. The neck is extended and the face is turned to the opposite side. The position of the common carotid artery is indicated by a line drawn from the upper part of the sternal end of the clavicle to a point midway between the tip of the mastoid process and the angle of the mandible. An incision is made beginning at the thyroid cartilage, along this line and extending downward about 8 cm. The skin, superficial fascia and platysma are incised and retracted and the ribbon muscles are retracted. The face is turned upward. The anterior border of the sternocleidomastoid muscle is then retracted laterally. If the muscle is not retracted it is often difficult to locate the artery that lies under the muscle. The artery is located by palpation, the sheath is isolated and incised and the carotid artery lying medially, the internal jugular vein laterally and the vagus nerve posteriorly and between are exposed. An aneurysm hook is then passed beneath the common carotid artery. Two pieces of umbilical tape are soaked in sterile liquid petrolatum, threaded on the aneurysm needle and passed beneath the vessel above and below the point of injection. These are used as traction sutures and remain in place. The portion of the artery to be injected is then drawn into view by making traction on these sutures and a 23 gage 1½ inch hypodermic needle attached to a 10 or 15 cc Luer syringe is inserted into the vessel and blood is drawn into the syringe. The injection is given slowly. The wound is flooded with sterile liquid petrolatum a small piece of petrolatum gauze dressing is placed into the wound the two pieces of umbilical tape are tied loosely over the gauze and another gauze dressing and bandage are placed over all. When it is desired to repeat the injection the new adhesions are carefully broken up with a gloved finger the vessel is brought into view by traction on the tapes and the injection is repeated. By using this procedure the authors have been able to administer serum dextrose, Prelo's solution of iodine and acriflavine base without injury to the vessel. They are of the opinion that the intima suffered less injury than any other portion of the artery. The media showed areas of necrosis, lumenization and infiltration with various

cells. The adventitia seemed to bear the brunt of pathologic changes, showing necrosis, infiltration and almost approaching abscess formation. Both carotid vessels should be utilized in order to bring the medicaments in contact with the two sides of the brain. The arteries can stand a reasonable amount of trauma provided care and caution is exercised. There is no doubt that a certain amount of damage is done to the carotids following intracarotid therapy; however, this should not deter any one from employing this method in the treatment of meningitis.

Simplified Oleothorax—Josenwich uses oil of cajuput, U S P X, rectified, which is water-white. It is well to incorporate, as necessary in proper amount various dyes or antiseptics such as acriflavine, carmine, methylene blue, metaphen, acriflavine hydrochloride, iodized oil, or others, to assist in the early detection of pleuropulmonary perforations or to add antiseptic properties to the solution. The author has found it convenient to prepare suitable quantities of colloidal solution, preferably employing a colloid mill. The solutions are put in ampules of various sizes. These are easily cleansed and warmed before using. He considers it advisable to inject from 1 to 4 cc of from 1 to 5 per cent of the essential oil in liquid petrolatum as the initial dose. The colloid solution requires little pressure on the plunger and permits the use of needles of the smallest caliber. Subsequent quantities are injected in arithmetical progression at intervals of one week or longer. If pus is present, moderate amounts should be removed at each treatment. The most reliable means of checking the status of the oleothorax is the fluoroscopic control before and after injection of oil, as well as in the interim.

Osteochondromatosis—Smith points out that, in osteochondromatosis, the knee is the joint most commonly involved and the condition is usually monarticular. It is a disease of adult life, and the majority of opinion is that it is of neoplastic origin. The joint may show no gross lesions other than the presence of loose bodies free within its cavity, or the joint may be characterized by a synovial membrane showing proliferations. These are hypertrophied villi containing cartilaginous and osteocartilaginous bodies. The two conditions may be found associated, the joint showing proliferations of its synovial membrane, together with free bodies within the joint cavity.

The loose bodies have their origin within the villi. Some are of fibrocartilage, some of fibrocartilage with bone in the interior, and some are of pure bone. The patient suffers from attacks of locking of the joint with severe pain due to the bodies becoming caught between the articular surfaces. Crepitation with movement of the joint may be noticed. The motion of the joint is restricted if the involvement is extensive. Palpation may or may not reveal the presence of the loose bodies. The treatment consists of the removal of the loose bodies by open operation. If there is extensive involvement of the synovial membrane, it is necessary to remove this as well. The author reports such a case in which numerous loose and pedunculated bodies of varying size were removed. Healing was by primary intention. Passive motion was begun on the third day. The patient was discharged from the hospital on the eleventh day and active motion and use of the leg was allowed after the third week.

Injection of Sporozoites in Malarial Therapy—Mayne states that malaria sporozoites isolated in suspended mediums from salivary glands of mosquitoes kept for periods of from one hour to five days and one hour reproduced malarial fevers when injected intravenously into patients for the purpose of malarial therapy. The reactions and subsequent clinical histories appeared to be no different from those occurring in cases treated with bites of infected anopheline mosquitoes. The three species of Plasmodium—tertian, estivo-autumnal and quartan—were thus successfully reproduced. The medium used in these instances consisted of sodium citrate alone or mixed with

freshly drawn, defibrinated human blood, enriched with a 1 per cent solution of dextrose. In these tests all attempts at mixing the sporozoites with glycerin and sodium chloride treated in identical manner were unsuccessful. Sporozoites kept in suspended cultures at temperatures below 42 F did not prove viable on human transplantation. In developing malarial therapy, practical difficulties were encountered when mosquitoes were applied by biting. After a preliminary test of a suitable medium for the maintenance in vitro of dissected-out sporozoites, an attempt was made to determine the length of time sporozoites from the salivary glands of insects may remain viable. More than fifty experiments were made. Malaria was produced in sixteen patients injected with the contents of the salivary glands of from one to three mosquitoes. In two instances successful injections resulted from the use of the sporozoites (of one mosquito) held in vitro at intervals of from one to three days. In all the tests the suspended mediums were maintained uniformly at a temperature of from 48 to 52 F. The clinical incubation periods developing from the inoculations, whether intravenous or intramuscular (subscapular), were from twelve to sixteen days in the estivo-autumnal strain, from thirteen to twenty-two days in the tertian and thirty-two days in the quartan. The parasite incubation was found to be from thirteen to fifteen days in the estivo-autumnal, from thirteen to twenty-two days in the tertian and thirty-three days in the quartan type.

Standardization of Roentgen Dosage.—Stenstrom and Lohmann state that, in order that a chemical method for measurements and standardizations of roentgen dosage may become practical, these requirements must be fulfilled: 1 Absorption and scattering of roentgen rays in the medium must approximate that of the tissue. 2 The chemical change to be measured must have a simple relation to the dose. 3 The medium must be stable enough so that it may be kept for a few days before measurements are made. 4 The method for determining the amount of change must be relatively simple and should permit determination of the dosage to an accuracy of at least 5 per cent. 5 The medium should be easy to obtain and reproduce. 6 The change needed for measurements must be produced by a reasonable dose. 7 A fairly small amount of solution should be sufficient for each exposure. The authors believe these requirements can be fulfilled by a properly prepared solution of methylene blue. Methylene blue was chosen because it was influenced considerably by irradiation and owing to the fact that the color change could be measured simply and quickly by means of a spectrophotometer. About 0.0016 mg of methylene blue per cubic centimeter of water was found to be a suitable concentration. A spectrophotometer was used to determine the absorption curve. After it had been found that the maximal absorption was in the red region at a wavelength of about 0.700 mμ (7000 angstrom units), it was considered necessary to measure the absorption at this wavelength only and to use this absorp-

tion as a measure of the concentration and of the change due to roentgen irradiation. With an absorption tube 10 cm long the extinction coefficient before irradiation was found to be 0.316. Since the color of methylene blue is to some extent affected by exposure to light, it is necessary to keep the solution in light-resistant containers until the time comes to make the measurements. If care is taken, the solution will keep for at least several weeks. For the experiments about 30 cc of solution was sealed in a glass container and placed inside the X-ray tube drum at a distance of 65 cm from the target. No filter was used. The voltage and the current were usually kept at 200 kilovolts and 30 milliamperes, respectively.

Tumor Histology and Bone Metastases.—The study of twenty unselected cases of tumor suggests to Downs and Hastings a theory to the effect that if the primary tumor has the property of exciting a marked desmoplastic reaction in its growth, this property will manifest itself when bone metastases appear and will stimulate a sclerosing type of lesion, also that the anaplastic, highly cellular tumors produce osteolytic changes in their bone metastases. There are various gradations of desmoplasia and anaplasia, and the large percentage of primary neoplasms are both anaplastic and desmoplastic. Accordingly, in the majority of cases both destructive and sclerosing lesions are prominent. It would seem rational to believe that, if the primary tumor cells have the power to excite the growth of fibroblasts and young connective tissue, these cells, when lodged in the bones, would likewise stimulate the formation of osteoblasts which are closely akin to the fibroblasts. The authors do not agree with Kaufmann and others that epithelial cells can possibly become osteoblasts. There are certainly numerous other factors concerned in the development of osteolytic and osteogenic metastatic lesions. The age of the patient, pre-existing constitutional diseases and endocrine disturbances undoubtedly have their influences. Along this line the authors propose to make a study of the calcium metabolism in these cases, in an attempt to determine what part if any, is played by the parathyroids.

Use of Cortin in Acute Hyposuprarenalism.—Robbins reports a case of acute hyposuprarenalism as a complication of acute streptococcal sore throat. The results of treatment, with cortical extract, of the case reported and of cases of typical Addison's disease, differed in only two respects: the blood pressure returned to normal limits and has been maintained there and the patient required no treatment for over three months and has steadily improved. For these reasons and because the complications of the kidney cleared up so promptly, the author feels that the damage to the suprarenals was toxic and temporary and that no permanent pathologic change has resulted. However, he believes that the cortin was essential to maintain life during the temporary abatement of the function of the suprarenals. Patients suffering from chronic hyposuprarenalism complain of lowered blood pressure, from 90 to 110 systolic; lack of energy and ambition, rapid fatigue on exertion, vague gastro-intestinal symptoms with no pathologic background, mental depression, and so on. The usual diagnosis in these cases is neurocirculatory asthenia. The author has been treating these patients with whole suprarenal substance with encouraging results.

Postoperative Lung Complications—Negus discusses the conditions that directly concern the anesthetist and the bronchoscopist. They are aspiration of the foreign body, diffuse suppurative bronchitis, abscess of the lung and bronchiectatic abscess, acute massive collapse or atelectasis and multiple bronchiectasis. He concludes that postoperative complications of the lung calling for bronchoscopy are not frequent, because suitable precautions are taken by most anesthetists and surgeons. However, a certain number of cases occur that are sometimes diagnosed as pneumonia but are actually due to the mechanical obstruction of a bronchus. Suspected cases require bronchoscopy for diagnosis and respond well to treatment by aspiration and direct intubation. All cases due to a foreign body can be cured, and most operative abscesses of the lung clear up quickly. Diffuse bronchitis is improved and its cessation prevents the subsequent development of multiple bronchiectasis. Acute massive collapse is in many instances the result of occlusion of a bronchus by a plug of thick mucus, the removal of which effects a cure.

Röntgen Treatment of Cancer of Lung—Roberts reports nine cases of malignant disease of the lungs in which roentgen treatment was used. In six cases the plant used was a double coil, giving a potential of 180 kilovolts, filter 0.5 mm of copper plus 1 mm of aluminum, focus skin distance, 23 cm, applicator circular, with a diameter of 8 cm. The other three patients were treated with a condenser plant giving a constant potential of 200 kilovolts, filter 1 mm of copper plus 1 mm of aluminum, focus skin distance, 30 cm, applicator rectangular, 8 by 10 cm. These conditions gave at 10 cm depth of water about 30 per cent of the skin dose. Treatment was given weekly or biweekly to one, two or sometimes three fields at each sitting, the dose to each field being from 75 to 80 per cent of the erythema dose. The fields were selected according to the position and extent of the tumor as revealed by roentgen examination and were varied so as to produce an even irradiation over the whole of the skin field. Such intensive treatment produced a deep and fairly uniform tanning of the skin. The amount of radiation was limited only by the tolerance of the skin, for since these patients cannot be cured the danger of later after-effects to the skin does not arise. With the exception of the one patient whose condition was already advanced, none of the patients have suffered any ill effects from treatment. The author is convinced that cases such as these cannot be treated on a preconceived idea of a "cancer dose." Irradiation must be carried out up to the point of saturation. Every month or in some cases twice a month roentgenograms were taken under standard conditions and the tumor was measured. The author concludes that in malignant disease of the lung roentgen treatment, if carried out intensively, causes temporary recession of the primary tumor, reexpansion of the collapsed lung and disappearance of the enlarged cervical glands. Whether it prolongs life or not, it certainly provides a survival period of a comparatively high degree of comfort, the inevitable end being rapid instead of a prolonged agony.

Cystic Hygroma Treated by Sodium Morrhuate—Harrower chose sodium morrhuate in the treatment of a case

of hygroma, because it occurred to him that one of the more modern sclerosing fluids might be effective. He believed sodium morrhuate to be least destructive to the subcutaneous tissues in the event of leakage. The swelling was aspirated and 4/10 ounces of brownish fluid withdrawn, and 2 cc of a 5 per cent solution of sodium morrhuate was injected into the cyst. The next day it was seen that the cyst was filling again, and the swelling had increased to more than half the size it was before aspiration. On the following day there was no further increase, and on the third day following the injection of the sclerosing fluid the swelling was definitely smaller. Six days after the injection of the sodium morrhuate solution, swelling was considerably reduced, and on the following day the cyst was again aspirated. About 2 ounces of fluid of similar appearance but somewhat thicker in consistency was withdrawn and 5 cc of the sodium morrhuate solution was injected. The next day the swelling had increased slightly, apparently owing to the irritation of the sclerosing medium. Thereafter the growth gradually subsided. The skin around the site of injection was treated periodically with methylated spirit and talcum powder and it slowly recovered its vitality. The tumor disappeared at the end of a month, also the nodules in the submandibular region, and only a small area of inflamed skin remained. Throughout the entire treatment the child showed no systemic inflammatory reaction and its health was in no way affected. The pulse and temperature remained normal, except for a few days, when enteritis developed with green diarrhea, which was quite unconnected with the injection treatment. The author is of the opinion that sodium morrhuate offers an easy and safe method of treating cystic hygroma.

Friedman Test for Pregnancy—Bishop describes his modification of the Friedman reaction, in which an adult female nonpregnant rabbit is employed. For the diagnosis, 10 cc of urine is injected intravenously. After an interval of at least thirty-six hours the abdomen of the animal is opened in the midline under ether anesthesia and the ovaries are inspected, care being taken not to displace them for fear of damaging the blood supply and thereby preventing them from being stimulated by any subsequent intravenous injection of urine. The abdomen is then closed in one layer with catgut or Chinese silk, and the skin is sewed up with Chinese silk. The wound is painted with alcohol. Should hemorrhagic bodies be absent at this first laparotomy, the rabbit is injected with urine obtained from a woman known to be pregnant and after a further interval of at least thirty-six hours the rabbit is submitted to a second examination. If on this occasion hemorrhagic bodies are still absent, the animal is considered resistant to urine of pregnancy and discarded, the test being repeated on another rabbit. If hemorrhagic bodies are present at the first laparotomy the test is positive. If they are present at the second laparotomy but not at the first, the subject is not pregnant. The experimental studies with this test show that 1 The active principle in the urine on which this test depends remains potent for at least six days after the urine has been voided. 2 The Friedman reaction is positive as early as twenty-one days after conception. 3 It becomes negative between forty-two and forty-eight hours after parturition. 4 Blood from the umbilical cord does not give a positive reaction. 5 Mechanical stimulation of the neck of the uterus in the rabbit tends to produce fresh yellow bodies, whereas the injection of urine of pregnancy almost invariably produces hemorrhagic bodies. 6 Cerebrospinal fluid obtained from a pregnant woman does not give a positive reaction. 7 The equivalent of 1/300 cc of urine may give a positive reaction in a case of chorionepithelioma. 8 If a pregnant rabbit is used as the test object, the result may be relied on if it is

positive, but if a negative result is obtained the test should be repeated. 9 Urine in cases of disorder of the pituitary may contain an excess of prolan.

Value of Levulose and Galactose Tolerance Tests—To determine the values of the levulose and the galactose tolerance tests for estimating hepatic efficiency, Rao investigated a number of patients and found that the levulose tolerance test gave positive results in a greater number of cases with liver disease than in those without evidence of hepatic disorder. In some cases with definite evidence of liver disease the test gave negative results and hence the author concludes that the test cannot be considered of diagnostic importance in any individual case. He thinks that the variable results obtained by the levulose tolerance test in cases of cirrhosis of the liver are due to the regeneration of the hepatic tissue and that a negative test in these cases cannot exclude liver disease as it indicates only that a sufficient amount of actively functioning liver tissue is left to maintain the carbohydrate metabolism. The test becomes positive only when there is diffuse destruction of the hepatic parenchyma together with failure of regeneration. Though the galactose tolerance test of Bauer has its own advantages, it is misleading to depend on the urinary observations alone and the total amount of galactose excreted in the urine is too variable to permit it to be considered a guide to hepatic efficiency.

Polyneuritis in Pregnancy—Ungley describes a syndrome consisting of lower motor neuron paralysis of irregular distribution, preceded and accompanied by sensory disturbances which affected three members of a family at different times over a period of twenty years and showed a marked tendency to recur after childbirth. The mother developed unilateral wrist drop

at the age of 39, a few days after the termination of her fifth pregnancy, having suffered from severe pains in the affected arm for three months previously. Similar pains had occurred at the age of 26, but without loss of power. Now, twenty-one years later, there is some residual paralysis of the extensors of the wrist and fingers. The younger daughter, at the age of 23 suffered from similar pains in one shoulder and arm during the latter months of her first pregnancy with rapid involvement of the other limb after parturition, and subsequently showed in the upper limbs asymmetrical wasting of peculiar distribution with localized areas of anaesthesia, gradual but almost complete recovery followed. The other daughter, at the age of 29 had pains in the right shoulder and arm followed soon afterwards by wrist drop and by paralysis of the small muscles of the hand on the affected side. Pains and localized anaesthesia occurred in the opposite arm. Recovery followed and she married. Two weeks after the birth of her first child pains recommenced in both shoulders, with paresis of both deltoid muscles. Wrist drop again developed, this time on the left side, and was followed by extensive but asymmetrical wasting of both shoulder girdles and of other muscles of the upper limbs. The subsequent recovery has been almost complete. Investigations have so far failed to throw any light on the etiology. The possibility of lead or some other extrinsic toxic substance as an etiologic factor is not likely as there has been no evidence of such intoxications. There have been no signs of syphilis or other infection of toxemia of pregnancy or of vitamin B deficiency. Examination of the cerebrospinal fluid, gastric contents, blood and urine has revealed no significant abnormality. Hematoporphyrinuria has never been a feature of these cases. No cervical ribs and no changes in the vertebral column were visible on roentgen examination. There are no nodules to be felt along the peripheral nerves, such as might suggest hypertrophic neuritis.

Complement Fixation Experiments on *Corynebacterium Diphtheriae*—Menton and his associates in their complement fixation experiments on 200 strains of *Corynebacterium diphtheriae* used saline suspension antigens prepared from twenty-four hour smooth cultures grown on agar and killed with formaldehyde. The antiserums were prepared from rabbits and the hemolytic system consisted of washed red blood cells of sheep and amboceptor (titer 1:2,000). Owing to the close relation of the grave, mild and intermediate types, cross tests were necessary to obtain any type indications. The tests were graded by diluting the antigen but in order to get reliable comparisons each antigen was carefully standardized by the opacity method. The tests were incubated for forty-five minutes in the water bath at 37°C, the hemolytic system was added, and the results were read after a further incubation of thirty minutes. The authors found that the serologic relation between the three types is close. The grave type was more antigenic than the other two. To obtain fixation with their antigens of *Corynebacterium diphtheriae* and their corresponding antiserums the bacterial suspensions had to be used ten times as strong as those required for the salmonella experiments. The grave type proved to be more distinct than the other two. Of these strains 95 per cent in the first 100 strains and 68 per cent in the second gave

results true to type. The typical "intermediate" strains were more closely related to the grave type than were the mild strains. Of the twenty-seven intermediate strains tested, seven gave grave results, and of the eighty-three mild strains tested only three gave grave results, but these were in the first 100 strains in which an intermediate serum was not used. When three serums were used not a single mild strain gave a grave result. Individual intermediate and mild strains varied greatly in antigenic activity. Some mild and intermediate strains could be separated only into groups rather than into definite types. This is particularly shown by the results obtained from mild strains when three serums were used. Only 29 per cent gave results true to type, 29 per cent gave intermediate results and 42 per cent gave no indication whatever. Of the twenty-three irregular strains in the second 100 strains which could not be classified by the Leeds method, ten gave intermediate reactions, seven no indication three mild and three grave, showing that these irregular strains were heterogeneous antigenically. In the first 100 in which only grave and mild serums were used, twenty-three irregular strains were tested, of which twelve proved to be grave, eight mild and three gave no indication. It is likely that, had an intermediate serum been available in these cases, a large number of apparently grave results would have turned out to be intermediate and so given a closer correlation with the second batch of irregulars. Ten normal human serums fixed the three types feebly (1-4) and equally. In complement fixation with bacterial antigens, many micellulable factors are involved. The authors tried to control some of them by doing comparative cross tests with antigens prepared in an identical manner. There are, however, strain peculiarities which cannot be gaged accurately, such as the rate of autolysis and the physical conditions affecting adsorption. With these reservations, they contend that serologic grouping by this means does not coincide with the method of classification suggested by the Leeds workers.

Perspective in the Examination, Prognosis and Treatment in Heart Disease. N. W. Markwell—p. 97

*Trichomonas Vaginalis Vulvovaginitis. H. Jacobs—p. 111

Trichomonas Vaginalis Vulvovaginitis.—Jacobs believes that the best treatment for trichomonas is that in which the perineum, vulva and vagina are first cleansed with ether soap and then treated by topical applications of mercurochrome, methylene blue, brilliant green and glycerin, kaolin or an alkaline powder. Kleegman's treatment consists of the application of mercurochrome and Lassars paste. Sure and Bercey recently have reported promising results with the use of pulverized quinine sulphate. The author used hexylresorcinol in treating a sufficient number of cases, obtaining such immediate improvement and such rapid cure that it would appear almost specific in its efficacy. His technique has been as follows. The patient receives treatment on three successive days, then each alternate day for three more treatments. On the days when no treatment is given, the patient takes a vaginal douche of lactic acid, 1 fluidrachm to a pint of water. This is continued until the next menstruation, after which any discharge is examined. In many cases this has sufficed for a cure, but in some trichomonas was still present, although there was little discharge. These patients received a second course of treatment and cure was obtained. In one hospital patient with a severe discharge six treatments only, at intervals of one week, and the use of the lactic acid douche, resulted in cure. In every case the first application gave immediate relief. For the actual method great care must be taken to enable the solution to reach all folds after careful drying of the mucosa following the application of green soap. Only when the life history of *Trichomonas vaginalis* has been completely described will prophylaxis be understood and curative treatment rationalized.

*Traumatic Chylothorax. A. Mouchet—p. 386

Deep Plantar Phlegmons.—Constantini and Liaras state that every plantar phlegmon is an indication for immediate surgical intervention. Deep plantar phlegmons usually spread posteriorly in the calcaneotibiotarsal canal and upward between the two muscular layers of the calf, usually stopping at the ring of the soleus. Tibiotarsal arthritis is a common complication and thrombosis of the vessels in the calcaneotibiotarsal canal may occur. For the treatment of a marginal abscess of the foot affecting the abductor of the fifth toe, a large incision made early usually suffices. For a deep phlegmon that has not invaded the calcaneotibiotarsal canal, the sole of the foot should be incised from end to end, following the zone of greatest pain and stopping at the tibio-calcaneal canal. A dorsal counterincision, if there is edema of the back of the foot, is recommended. If the plantar phlegmon has spread to the calcaneotibiotarsal canal, an initial malleolar incision curving around the malleolus and just in contact with it should be made and the suppuration exposed. From here the purulent fistula should be traced in both directions. If the fistula follows the flexor tendon of the large toe, the incision should follow this tendon up to the digitoplatar fold. If, as usual, the suppuration spreads over the sole of the foot, the incision follows the axis of the foot parallel to the third interosseous space. Toward the leg the incision follows the interior surface of the tibia. The anterior gastrocnemius is pushed back, and the tibial insertions of the soleus are detached extensively exposing the deep vasculonervous tissues of the leg. In case of dorsal edema, dorsal incision is advisable and if pus has spread in front of the Achilles tendon an external incision behind the fibula is recommended. In case of synovitis of a toe or infection of a crushed toe with involvement of the plantar region, the sole of the foot should be incised in the direction of the calcaneal canal to the end of the purulent fistula. If there are osteo-articular complications, the tibiotarsal joint must be opened and the talus removed for drainage. Osteitis of the metatarsals demands amputation. If the general condition is alarming, amputation is the wisest procedure even if only a tibiotarsal arthritis is found.

Traumatic Chylothorax.—Mouchet studied forty-three cases of chylothorax reported in the literature. Of these, thirty-two were produced by internal trauma without open lesion. In twenty-one cases the chylothorax was on the right side, in seven it was on the left and in four it was bilateral, indicating that in most cases the rupture of the thoracic duct occurred in the lower part of the thorax. The rupture of the thoracic duct in most cases was produced by fracture of a vertebra, in one case by fracture of a rib and in one case possibly by fracture of the clavicle. In some cases chylothorax followed a trauma without the production of a skeletal lesion. In these cases the rupture of the thoracic duct probably resulted from overdistention of the duct favored by repletion during digestion. The author thinks that in the majority of cases the pleura is ruptured simultaneously with the thoracic duct and the chyle is aspirated directly from the ruptured canal into the pleural vacuum. Clinically, recovery from the shock of the trauma is followed by an interval of from three to four days without symptoms before the pleural effusion is revealed by the sudden onset of dyspnea, agitation, profuse sweats and cyanosis. Pleural puncture permits the withdrawal of chyle. Occasionally, cure follows a single evacuation, but usually each aspiration is followed by a new effusion, and loss of weight, oliguria and severe asthema lead to death from inanition. Eleven cases of chylothorax were caused by open lesions, usually located in the neck with the resulting effusions on the left side. In this form gaseous effusions, flow of chyle from the wound and infections may occur in addition to the other symptoms. Diagnosis is made by examination of the liquid of effusion to

determine whether it is chyle. The prognosis is grave, with 41 per cent of deaths in forty-three cases. Siphonage is to be avoided, as it favors eruption of the chyle. Generally, treatment should include a diet to reduce the production of chyle. Symptoms of compression demand evacuation, but this should be incomplete (except in case of shock) to avoid the return of the pleural vacuum. A small effusion requires no treatment, if it is abundant and recurrent, two or three aspirations should be made and, if the effusion still continues to be rapidly produced, thoracotomy is indicated. Injury to the cervical portion of the thoracic duct may require ligation or tamponade. Infection of the effusion demands thoracotomy with drainage.

Parenteral Protein Therapy for Gastroduodenal Ulcers

Pribram considers parenteral protein therapy the method of choice in the treatment of gastroduodenal ulcers. His opinion is based on an experience of thirteen years, covering more than 500 cases. He thinks that the effects of this therapy are attributable to the following modifications produced by the protein injections: (1) abolition of the muscular spasm and relative quietness of the ulcer with consequent disappearance of the pain and increase of the alimentary tolerance, (2) abolition of the angiospasm and hyperemia, (3) restoration of the inflammatory reaction in the region of ulceration, (4) increase of the capacity for regeneration of the tissues and (5) increase of the quantity of antipepsin in the blood. The author uses a crystallized vegetable protein, injected intravenously. The treatment consists of a total of not more than eight or ten injections, starting with a small dose to produce a slight general reaction and continuing with gradually increased doses given as soon as the signs of the previous reaction have disappeared. Improvement is sometimes noticeable after the first or second injection. Cures were obtained in from 60 to 70 per cent of the author's cases while some of the others were noticeably improved. All the patients were referred to him for surgical intervention because of the failure of medical and dietetic treatment. The success of the protein therapy has limited the indications for surgical intervention to emergency cases (perforation), cases presenting chronic hemorrhages and cases in which protein therapy has failed after a minimum of two series of injections. The only contraindication is tuberculosis, even the latent forms, as the injections may reawaken the foci of infection.

Injection of Urine in Allergic Diseases—Jausion and his associates state that the therapeutic injection of a patient with his own freshly collected and antiseptic urine (first reported by Jausion and Paleologue in 1929 under the term of auto-urotherapy) is more logical than autohemotherapy. In the urine are eliminated the endo antigens and exo antigens responsible for many allergic conditions, by reinjecting the urine into the patient it is possible to desensitize him to these antigens. As the urine is free from albumin (except in pathologic cases) it produces no shock. The urine is collected under antiseptic precautions and one drop of phenosalol or iodized alcohol is added for each cubic centimeter of urine. After mixture of the urine and the antiseptic has been obtained by repeated aspirations into a syringe it is allowed to stand for five minutes, this may be extended to thirty minutes for a urine with high bacterial content. The urine is then injected subcutaneously

or intramuscularly, in case of turbid urines injection should be subcutaneous. The injections should be given at intervals of from two to four days, with the dosage increased gradually from 0.5 to 5 cc. This therapy was successful in 336 of 372 cases of allergic diseases, including cases of migraine, pruritus, hay fever, asthma, urticaria, prurigo, strophulus, acute or chronic eczema, parakeratosis, psoriasisiformis and psoriasis. Auto-urotherapy is not effective in the driest forms of eczema or in parakeratoses. It is contraindicated in chronic suppurations, pyococcal skin diseases, anthrax, furunculosis, impetigo and ecthyma without eczematization. The urine also contains hormones capable of influencing the vagosympathetic system and to these the authors attribute the good results obtained in some cases of Raynaud's disease, intermittent claudication, insomnia due to sympathetic hypertonia, and so on. They think the auto-urotherapy causes a vagal discharge, liberating in hypervagotonia due to autogens, corrective in neurosympathetic dystonias. While contraindicated in extra-urinary infections in infections limited to the urinary tract auto-urotherapy is an effective way of vaccinating against the urinary bacteria, especially in descending pyelonephritis caused by the colon bacillus.

Heterotopic Ossifications—Ceccarelli cited a case of ossification occurring in an operative scar (supra-umbilical incision) and refers to the literature on the subject of heterotopic ossifications. The author attributes a certain osteogenic influence to hematomas. The products of albuminoid destruction in hematomas often bring about deposits of calcium salts leading to ossification. Hematomas are considered less important than operative wounds in the causation of ossifications. The author tried to follow the neoformative process of the heterotopic bone. He experimented with rabbits, in which the vasa pedicle and renal artery of the normal kidney were ligated, causing hydronephrosis, thus predisposing the kidney to ossifications. On the basis of this research, the author maintains that the formative elements of bone arise from the connective tissue through a process of indirect metaplasia. He stresses the importance of the presence of calcium salts in heterotopic ossification. The products of albuminoid decomposition are produced in necrotic degenerative foci in which calcium salt deposits are often found. These ossifications following trauma or operations are generally preceded by a disturbance in circulation. The circulatory modifications cause a reaction in the connective tissue with return to the embryonic state and cause the appearance of cellular elements (polyblasts and hemohistoblasts) in the area where the stimulus has acted. If these elements are found in a location rich in calcium salts, they may be differentiated not only as fibroblasts and chondroblasts giving rise to connective scar tissue but also as osteoblasts or chondroblasts giving rise to real osseous tissue through the contemporary appearance of the marrow series. The depositing of calcium salts is attributed to modifications of the pH of the ionic state of the colloidal state and of the area in which the salts are found dissolved. These biochemical modifications explaining the formation of calcareous concretions are not, however, the basis for ossification. The author maintains that the osteoblasts represent the trophic center of ossification and at times lend impulse to the change of the chemical state of the calcium salts which absorb the osseous tissue. Through the abnormal stimulus coming from particular biochemical modifications in a determined tissue the undifferentiated polyblastic cells receive an impulse which evolves toward the differentiated series up to the more complete and complex formation of it which is the osseous tissue containing marrow.

Effect of Splenectomy on Peripheral Circulation—Lucchese studied in rabbits the function of the spleen with reference to the peripheral blood and found that after splenectomy the same functional modifications take place as after sympathectomy of the splenic artery. He observed a temporary diminution of globular resistance, a marked increase in the number of platelets and a shortening of the coagulation time. Subcutaneous injections of epinephrine in rabbits not yet splenectomized showed an increase of leukocytes with a predominance of lymphocytes. Thus there was always a normal epinephrine lymphocytosis. After splenectomy there was a considerable increase of leukocytes with a predominance of neutrophilic polymorphonuclear cells. The same observation was made after periaarterial sympathectomy of the splenic artery when an epinephrine lymphocytosis was replaced by an epinephrine neutrophilic leukocytosis. The author states that following splenectomy as well as sympathectomy there is no appreciable modification of the number of erythrocytes, the number of leukocytes and the leukocytic formula, no bilirubin is found in the blood plasma and marked congestion and stagnation of the veins of the splenic pulp remain unmodified.

Prostatectomy in Nephrectomized Patients—Le Roy cites a case of prostatic hypertrophy and urinary infection of ten years' duration before the right kidney was resected for hypernephroma. Prostatectomy for adenoma was later performed in two stages. The author reviews the literature on the subject and states that cases are rarely found in which prostatectomy is performed on nephrectomized patients. He maintains that persons having lost one kidney show as much resistance to intoxication and infection as normal persons. In prostatic patients the imminent extirpation of a kidney does not constitute a contraindication for adenomectomy, provided the remaining kidney is healthy. In these cases, operation should be performed at once in order to avoid such complications as urinary infection and pyelonephritis.

Cholecystography According to Antonucci's Method—Zappalà describes the technique of Antonucci's method of rapid cholecystography (*Policlínico* [sez med] 40 128 [Feb 1] 1933, abstr *THE JOURNAL*, April 15, 1933, p 1212) and reports the results of his experiments on 300 patients and normal persons. Operative control of 100 of the patients demonstrated perfect correspondence between the degree of alteration of the wall of the gallbladder and its degree of roentgenologic opacity. In healthy persons it always showed positive results. The author states that Antonucci has not introduced a new contrast medium but has added dextrose, which accelerates the velocity of elimination of the color medium from the liver. The author's experiments reveal that the greater velocity of elimination of tetraiodophenolphthalein in the Antonucci method is determined by a more rapid transfer of the substances of the liver to the bile. The fundamental fact determining this is hyperglycemia, but the mechanism through which the liver passes the color medium to the biliary tract still remains obscure. Several authors state in this respect that dextrose exercises a stimulus on the hepatic cells. The author does not accept this interpretation, since the hyperglycemia of a diabetic patient determines a rapid cholecystography and there certainly can be no stimulus of the dextrose on the hepatic cells in diabetes. The administration of the Antonucci method is simple and the disturbances that may arise are not different from or more serious than those encountered in the intravenous method of Graham. The advantages of this method lie in its great sensitivity, its rapidity and its revealing of slighter cholelithic diseases. The method possesses great precision and can always be applied in doubtful cases of gallbladder disease for definite diagnosis.

*Chorio Epithelioma with Positive Results of Aschheim Zondek Test Case P Sa—p 306

Chorio-Epithelioma and the Aschheim Zondek Test—Sa states that the concentration of hypophyseal hormones in the urine of pregnant women is lower than that in the urine of women having uterine mole or chorio epithelioma. The persistence of positive results of the Aschheim-Zondek test with a concentration in hormones higher than that which may be an indication of an intercurrent pregnancy, following a molar abortion either complete or completed by means of curettage, is a diagnostic sign of the presence of chorio-epithelioma and a therapeutic indication for the performance of a total hysterectomy, even in young women. The author's patient, aged 22, had an incomplete hemorrhagic molar abortion, which was finished by means of curettage. The hemorrhage ceased and the patient was discharged from the hospital, apparently cured. After this event, however, she presented a condition of incipient cachexia. The Aschheim-Zondek test, performed thirty eight and fifty-three days after the molar abortion, gave positive results with a high concentration of prehypophyseal hormones. Total hysterectomy was followed by complete recovery. The patient gained weight and there was a great improvement in her general condition. This improvement has persisted one year after the operation and no metastases have appeared. The histologic study of the uterus removed at the operation gave a diagnosis of chorio epithelioma.

Case of Rudimentary Scleroderma and Calcareous Gout K Steiner—p 142

Endocrine Disturbances in Thrombo-Angitis Obliterans—Three cases of Bürger's thrombo angitis obliterans were studied by Nusselt. From observations on the epinephrine and sugar content of the blood in these cases he assumes a hyperepinephrinemia. A hyperfunction of the suprarenals has likewise been assumed in Raynaud's disease which presumably is related to Bürger's disease. On the other hand, resection of the splanchnic nerves, which according to some authorities reduces the production of epinephrine, has effected favorable therapeutic results in Bürger's disease. The vasodilatory, pancreatic circulatory ferment, the antagonist of epinephrine which other authors found helpful in Bürger's disease, failed in the author's cases. He believes that the hyperthyroid sympathetonic metabolism which he observed in these cases of Bürger's disease is probably the constitutional foundation of the disease.

Cutaneous Epinephrine Reaction—Sella shows that the human skin is highly susceptible to epinephrine. Epinephrine introduced into the organism by iontophoresis probably stimulates the suprarenals to increased elimination. Thus epinephrine is mobilized in the organism for a shorter or longer period, and the duration of this mobilization can be controlled by cutaneous tests. The injection of the serum of a person who has been treated with epinephrine produces a white spot. The reactivity of the skin can be changed by epinephrine for the

injection of a morphine solution into an epinephrinized skin either produces no reaction or weakens it considerably. It is probable that the action of the absorbed epinephrine can be intensified by the skin. The author points out that for some time it has been assumed that the so-called angiotrophoneuroses are caused by a constrictor substance particularly by epinephrine. Recently this group has been enlarged by Pals vascular spasms, by essential hypertension and by other disorders. The author emphasizes that in the so-called hyperepinephrinemic disturbances not only the quantitative determination of epinephrine is important but its production also should be considered, for it is probable that the subsequent changes are primarily the result of the increased production. In essential hypertension, in Raynaud's disease and in acrocyanosis with hyperthyroidism, an increased production could be demonstrated, and the same was true in some skin diseases, in pruritus, in some cases of chloasma of the face and in a case of psoriasis. In allergic skin diseases, such as chronic urticaria, the values were either normal or subnormal. The author suggests that these observations eventually may be utilized in the therapy.

Pathogenic Significance of Enterococci—Gundel gives a short survey of the microbiology of enterococci and indicates their position within the group of streptococci. He applies the term enterococci to all intestinal streptococci but he excludes the hemolytic streptococci that occur only rarely in the intestinal tract. The enterococci grow in the usual culture mediums in two types (A and B). Type A grown on blood agar is characterized by delicate blackish small to medium sized colonies with a whitish center and by a changing but generally a slight green zone in the culture medium. Type B, however, shows a much more luxuriant growth; it appears in whitish staphylococcus-like colonies usually surrounded by a fine black zone. Thus there are considerable cultural differences between the two types, but, since the examination of hundreds of strains reveals numerous transitional types the difference becomes somewhat less distinct. The author shows that, since streptococci of the same cultural behavior as the enterococci occur also in parts other than the gastro-intestinal tract it is really illogical to apply the special term enterococci to the intestinal streptococci and he thinks that to speak of pleomorphic streptococci of type A or B would be more correct. He discusses the pathogenic significance of the enterococci. He stresses particularly the role of enterococci in the inflammatory changes of the biliary tract and discusses enterococcic peritonitis and the significance of enterococci in appendicitis and in infections of the urinary system such as cystitis and pyelitis. He admits that some investigators deny the causal significance of enterococci in some of these disturbances but he thinks that this is not justified if enterococci are seen in pure culture as the causal organisms of septicemias. The detection of the enterococcus may lead to the discovery of the focus of infection in the biliary tract, in the intestinal tract or in the urinary passages.

Intussusception of Colon as Complication of Dysentery—Holzmänn tells of a nursing aged 8 months who contracted dysentery. The stools contained mucus pus and blood and spasms of the colon could be felt. According to X-ray a spastic condition of the colon is quite frequent in

dysentery. The nursing's condition improved gradually, but on the fiftieth day of the dysenteric disturbance a sudden hemorrhage and prolapse from the anus occurred, a tumor was noticeable above the symphysis and bilious vomiting set in. On the basis of these symptoms the case was diagnosed as a colic sigmoidal intussusception, and this diagnosis was corroborated by digital examination. Treatment of the intussusception was followed by cure. The author thinks that the otherwise rare colic intussusception is readily understandable in cases of this nature. The portion of the intestine that has become spastically contracted as the result of the dysenteric inflammation becomes invaginated into the more flaccid portion.

Toxemia Following Thoracoplasty—Domanig states that, after a thoracoplasty, a considerable number of his patients with pulmonary tuberculosis developed transient symptoms apparently the result of the action of toxins. The same symptoms can be occasionally observed in florid pulmonary tuberculosis and after high doses of tuberculin. These manifestations occur with greatest frequency in patients who develop complications of inflammatory nature in the postoperative period. The two at times appear simultaneously. A definite relation could not be established between the state of circulation in the postoperative period and these late toxic symptoms. Bacillemia was demonstrated by the culture method to be present in 15 per cent of the patients before the operation and in 20 per cent after the operation. Apparently bacillemia was not the cause of the toxic manifestations. There was noted a tendency to diminution of allergy to tuberculin following thoracoplasty. This was particularly the case in patients whose postoperative course was complicated by severe inflammatory states. Such patients are likewise particularly prone to exhibit manifestly toxic symptoms. The postoperative rise in allergy is to be regarded as an unfavorable prognostic sign. The author found that fresh serum of phthisical patients was more often fatal to the mouse than the serum of healthy persons. The toxic effect was greater when serum was taken from patients who had had a thoracoplasty particularly when complicated by severe inflammatory reactions. Watery extracts prepared from an extensively involved tuberculous lung were found to be definitely more toxic than those prepared from mildly diseased or from normal pulmonary tissue. The question of whether this toxic effect is the result of some specific tuberculous toxin could not be definitely answered.

Bloodless Reduction of Congenital Hip Dislocation—Becker points out that in an analysis of the results obtained from bloodless reduction of congenital hip dislocation it is essential to differentiate between those obtained at the end of treatment and those present at the end of the period of growth. The latter are, as a rule much worse than the former. He reports sixty-seven cases presenting ninety-seven dislocations treated within the first thirty years at the Erlanger clinic. The Lorenz technic of bloodless reduction was followed. In a group with a lapse of twenty years 75 per cent had a poor result and 40 per cent had a recurrence of the dislocation. Only one eighth of the cases showed anatomic healing. In all the anatomically healed cases operation was performed below the age of 3½ years. The author demonstrated in patients with a recurrence as well as in those with subluxation only the existence of pronounced alterations in the upper part of the femur and in the acetabulum such as flattening of the head of the femur, anterior torsion and coxa vara. He demonstrated by roentgen studies that even in the more favorable cases there

were changes in the femur and in the entire half of the bony pelvis. He regards it as a proof that this entire skeletal section was the seat of a developmental defect. In another group with a lapse of only five years since the reduction, five showed anatomic healing, fifteen a mild subluxation, seven a pronounced subluxation and seven an actual recurrence of dislocation. In spite of it, however, with the exception of three, the rest had excellent functional results. He concludes that the patients with mild subluxations and excellent functional results develop in the course of growth severe subluxations which finally lead to recurrence of dislocation. The excellent results here were only temporary. Only anatomically healed cases present a favorable outlook for a permanent cure. Even the mildest subluxation may lead in the course of growth to recurrence of dislocation. The author believes that the end-results may be improved by the early detection of subluxations and the application of orthopedic measures to prevent their further development.

Hypochloremic Coma in Nurlings with Pylorospasm—Among thirty-four nurlings with pylorospasm, observed by Seckel in the last eighteen months, there were several with peculiar disturbances of the consciousness and with abnormal respiratory movements. This hypochloremic coma, called also coma pyloricum, was studied carefully by the author. He mentions the following as the clinical characteristics: (1) disturbances in the consciousness manifested by somnolence, apathy, sopor and coma; (2) respiratory disorders, such as slow and superficial respiration, apnea, hiccup and yawning; (3) muscular hypertonia and nontetanic spasms. The metabolic anomalies are exsiccosis, which is evidenced by loss of turgor, anhydremia and albuminuria, chloropenia, manifested in achloruria and hypochloremia, hyposmosis, which is partially compensated by alkalosis, and azotemia, which, however, is rarely severe and may be absent. In patients without coma, the metabolic changes are similar but of a much milder degree. Organic pyloric stenosis in adults and in older children and induced pyloric occlusion in animals are accompanied by essentially the same comatose manifestations and by hypochloremic-alkalotic metabolic disturbances. In adults, gastric spasms and "chloroprivic nremia" predominate. The hypochloremic coma of pylorospasm has to be differentiated from the coma that occurs in alimentary intoxication. The latter form is usually hyperchloremic acidotic and, in contradistinction to the superficial respiration of coma pyloricum, it is characterized by forced respiration. For the differentiation of pylorospasm from other conditions characterized by vomiting, examination of the chloride metabolism is recommended.

Reaction in Meningitic Cerebrospinal Fluid—While studying the factors influencing the surface tension of the cerebrospinal fluid, von Ambrus observed certain reactions that he considers suitable for diagnostic purposes. He made his studies on normal and on meningitic cerebrospinal fluid and employed well water and distilled water as controls. In three series of test tubes the first contained well water, the second distilled water, the third normal cerebrospinal fluid and the fourth meningitic cerebrospinal fluid. In the first series, for each 1 cc. of fluid he added 0.1 cc. of a 2 per cent distilled aqueous potash soap colloid. The well water shows opalescence, turbidity and flocculation, but, owing to the variation in the composition of the well water, these changes are not constant. The distilled water opalesces slightly. The nonmeningitic cerebrospinal fluid shows a decided turbidity, while the meningitic fluid shows only an opalescence. The turbidity in the nonmeningitic cerebrospinal fluid is due to its low protein content, which provides only a slight colloidal protection for the cations of the cerebrospinal fluid and thus facilitates the action of potash soaps. The author asserts that this reaction is suitable for diagnostic purposes.

He describes the various changes observed in the four test tubes of the second and third series. In the second series he added for each cubic centimeter of fluid 0.1 cc. of a 20 per cent sulphosalicylic acid, and in the third series 0.1 cc. of a 2 per cent distilled aqueous potash soap colloid as well as 0.1 cc. of 20 per cent sulphosalicylic acid. He states that he has employed the reaction of the second series for a number of years, and he considers the reaction of the third series the most suitable one. Because of its simplicity he recommends the reaction for use in general practice.

Menopausal Edema—Curschmann characterizes menopausal edema as transitory, not circumscribed but rather diffuse cutaneous swellings that gradually shade off into the normal portions of the skin. The swellings are usually rather pale occasionally of normal color, but never bluish or reddish. The sites of predilection are the hands and lower part of the arms but occasionally the legs below the knees are involved. The face is rarely affected. The edemas sometimes appear in the morning hours and disappear again in a short time, but they relapse again and again. As a rule they occur simultaneously with other psychoneural, sympathetic and vasomotor disturbances of the menopause. However, they may outlast the years of the climacteric and may relapse for a decade or more. The author states that since he has watched for this edema he has observed it frequently together with other disturbances of the menopause. Most women who had these swellings developed a morbid anxiety about renal or cardiac dropsy, and some physicians who do not understand the true nature of these edemas support the patients in their fear or may diagnose the condition as hypothyroidism. The author discusses two case histories and was able to demonstrate that the edemas were not of renal, cardiac or thyrogenous origin.

Postencephalitic Hyperkinesis—Münzer reports the history of a girl who is now 10 years old. The child presents a hyperkinetic syndrome, characterized by intermittent attacks of a tonic spasm in the region of the left facial nerve with synchronous dextral nystagmus of both eyeballs. In addition to this there are mild paresis in the region of the left facial, trigeminal and hypoglossal nerves, late symptoms of a paresis of the left upper extremity and trophosecretory disturbances evidenced by skeletal anomalies (left lower jaw, vertebral column), by cyanosis of the left side of the head and of the homolateral arm and by hyperhidrosis of these regions. The anamnesis revealed that the disorders dated back to a febrile disturbance during the sixth month of life, and the author assumes that this must have been an epidemic encephalitis. This is borne out by the acute symptoms, by the further course and by the fact that the disturbance occurred during an epidemic of encephalitis. The author considers the report of this single case warranted, because he found no analogous report in the literature and thinks that as a postencephalitic syndrome this form of hyperkinesis deserves attention.

Ileus Caused by Lymphogranulomatosis—Hammelmann reports a case of intussusception ileus caused by a lymphogranulomatous tumor in the upper jejunum. The operation disclosed a tumor the size of a small hen's egg. To loosen the intussusception proved difficult, and it became necessary to resect 40 cm. of the small intestine. Several enlarged mesenteric lymph nodes were also removed. The operation proved successful, but later the patient developed a transverse myelitis which resulted in paralysis of both legs and impaired the function of the urinary bladder, of the rectum and of practically the entire lower part of the body. The author thinks that this disturbance

of the central nervous system was likewise caused by the lymphogranulomatosis. He points out that cases of lymphogranulomatosis of the intestinal tract are relatively little known and that a case of ileus resulting from a lymphogranulomatous tumor has never been reported.

Treatment of A-Vitaminosis in Nurslings—Wieland reports the history of a male nursing, who developed dyspepsia when breast feeding was interrupted. In the course of the treatment for dyspepsia he was put on a diet of skimmed human milk. He became atrophic and developed a hemorrhagic diathesis and xerophthalmia with keratomalacia. In order to counteract the xerophthalmia, therapy with vitamin A was resorted to. The nursing was given ten drops of an oily carotene solution three times daily, but, although the hemorrhagic diathesis disappeared gradually, the eye disorder was not influenced by the carotene medication and was even exacerbated. Then the nursing was given whole human milk and, in addition to it, cream and cod liver oil. Under this treatment the weight increased and the photophobia and the discharge from the eyes disappeared. After three months the nursing's general condition had sufficiently improved so that he could be discharged from the hospital, but he was still anorectic. The author cites other examples of keratomalacia in nurslings who had been fed with skimmed milk and discusses various theories on the failure of the carotene treatment. He thinks that the nursing's eyesight might have been saved if cod liver oil had been given earlier.

Coronary Thrombosis in Diabetes Mellitus—Eschbach shows that the concurrence of disease of the coronary arteries with diabetes mellitus is more frequent than is generally assumed. He observed diabetes mellitus in 20 per cent of the cases presenting occlusion of the coronary arteries. On the basis of his observations in fifteen cases he rejects the opinion that diabetes mellitus complicating a disturbance of the coronary arteries is generally benign for he found it to be severe in most cases. If glycosuria is not detected until after the first signs of coronary thrombosis appear it is necessary to ascertain whether the glycosuria is really of diabetic origin, because coronary thrombosis frequently concurs with cerebral embolisms and thus the glycosuria may be of cerebral origin. The differentiation of cerebral and diabetic glycosuria is important for the therapy. In precomatose conditions with noticeable peritoneal manifestations, it may be difficult to determine whether a coronary thrombosis is present or not; only the complete success of the treatment directed against diabetic coma will exclude coronary thrombosis with certainty. The author discusses the influence of diabetic hyperglycemia and acidosis and of insulin on the heart and the circulatory apparatus. He states that intravenous administration of insulin should be avoided in case of concurrence of coronary disorders with diabetes mellitus, and that it should be given in small and more frequent subcutaneous doses. He also recommends intravenous injections of dextrose. If a comatose condition is absent it is best to treat the diabetes merely with dietary measures and try to dispense with insulin.

Treatment of Eczemas in Children—Gierthmühlen shows that the last three decades have brought great advances in the understanding of cutaneous disorders in children. The author

differentiates dermatitis intertriginosa, dermatitis seborrhoides and crusta lactea from true eczema. The latter occurs primarily in children between the third and eighteenth months of life. Most investigators consider it an allergic phenomenon, more particularly a nutritive allergy, and in order to treat this form of allergy correctly it is necessary to study the diet of the affected child for mistakes of a qualitative or a quantitative nature. It is essential to avoid overfeeding. In many instances it is possible to counteract the eczema by changing from whole milk to buttermilk or to skimmed lactic acid milk. The early addition of vegetables and fruit juices is advisable. If by changing from whole milk to buttermilk or skimmed milk the eczema does not disappear, other allergic factors, such as eggs, different types of flour or certain types of milk, must be searched for. It may for instance become necessary to replace cow's milk by goat's milk. Undernourished children with eczema have to be given adequate amounts of high-caloric foods. Eczemas in older children, which are frequently of a nervous origin, often yield to a vegetarian diet. However, nutritional therapy alone is not sufficient. The author considers ointments containing tar and powders helpful for local treatment. As especially effective he recommends a powder containing sulphur and tar. He found this preparation helpful in neurodermatitis of children of school age, but also in strophulus and in eczemas in which a pyogenic secondary infection has developed. In the latter conditions it is advisable to soften the crusts first by treating them with oil, and then to apply the tar and sulphur powder.

Treatment of Bronchial Asthma with Benzene—Kariakstis shows that benzene and benzene-like hydrocarbons are valuable therapeutic irritants. He reports the clinical histories of several patients with bronchial asthma, in whom the intramuscular injection of a preparation consisting of ten parts of purified petroleum benzene and thirty parts of olive oil promptly counteracted the asthma attacks. He considers the external quadrant of the buttocks, about three or four finger-breadths below the iliac crest, the most suitable site for the injection because there are few nerves in this region. It is advisable to give the injection quite deeply. The usual dosage is from 0.4 to 0.5 cc. In order to reduce the pain an anesthetic may be injected at the same time. The author asserts that the injections are generally well tolerated, for the focal reaction causes only slight subjective disturbances. The fear of abscess formation is entirely unjustified, as intramuscular injections of aliphatic hydrocarbons have a favorable effect on inflammatory processes. Furunculosis, for instance is favorably influenced by them.

Tubercle Bacilluria—Dimtza and Schaffhäuser apply the term tubercle bacilluria to the renal elimination of tubercle bacilli without tuberculous involvement of the kidneys. From observations on many cases they conclude that in case of renal elimination of tubercle bacilli there always exists an initial chronic caseocavernous tuberculosis of the kidneys and that tubercle bacilluria is out of the question. They found that during the incipient stage of chronic renal tuberculosis, owing to the still closed subcortical foci the intrapapillary foci or even the small open papillary foci a tubercle bacilluria may be simulated. This is understandable on the basis of necrotic controls, because tubercle bacilli can be bacteriologically demonstrated during the earliest stages in the smallest open ulcerous papillary foci. Moreover tubercle bacilli are eliminated from intrapapillary foci or from foci of the subcortical

medullary pyramids before leukocytes are eliminated in larger masses and while the renal function is as yet only slightly impaired. Although the authors consider the repeated demonstration of tubercle bacilli in the renal urine an initial symptom of an incipient chronic renal tuberculosis, they nevertheless demand that the definite diagnosis of renal tuberculosis should not be made and nephrectomy should not be resorted to until three factors have been established: bacilluria, pyuria and deficient function. In evaluating the various functional tests the authors state that the indigo carmine test, although helpful, is not absolutely reliable for the early diagnosis of chronic renal tuberculosis. Cryoscopy, refraction and comparative determination of urea likewise do not give reliable information about the renal function in the beginning stage of tuberculosis but do so only in the later course. The authors warn against the overevaluation of intravenous pyelography. They consider the premonitory albuminuria a much less important symptom than the demonstration of leukocytes.

Passage of Vitamin A into Milk.—Fasold and Peters studied the effects produced by a concentrated cod liver oil preparation when given to lactating rats. The nursing young rats showed a much better growth than the controls. They call attention to the favorable influence of cod liver oil on nursing mothers and state that several hundred observations have shown that in women who during the last months of gestation had been given additional quantities of vitamin A, the incidence of febrile complications is four times as small as in other women.

Fermented Tuberculin.—Konis shows that fermented tuberculin does not "whip" the foci as does ordinary, not fermented tuberculin. Fermented tuberculin produces a hyperemia at the focus and around it. This hyperemia promotes the cicatrization of the focus and has a favorable influence on the further course of the disease. The author paid particular attention to the hemoptyses that occur during treatment with tuberculin. He compared those occurring after the use of ordinary tuberculin with those following treatment with fermented tuberculin. He found that fermented tuberculin does not produce profuse or sudden hemoptyses, even when the injections are repeated, as is the case if ordinary tuberculin is used. The hemoptyses were not noticeably increased but their duration was somewhat extended. On the basis of this he maintains that the process is not a true focal reaction but rather a focal hyperemia.

Thyroid Activation by Serum from Pregnant Women.—A review of the literature convinced Schenk that the statements about the thyrotropic action of extracts from the urine of pregnant women differ widely, while the reports about extracts of the anterior lobe of the hypophysis correspond, the latter having been proved activating in all experiments. The contradictory reports about the extracts of urine induced the author to test a number of these substances and he obtained positive results with prolactin, prehormone and several other

extracts, while other investigators had obtained opposite results with prolactin and prehormone. He points out that the contradictory results may be due to the fact that the examiners have disregarded certain prerequisites of the test. He emphasizes that during the tests the guinea-pigs must receive a diet that puts the thyroid to rest. Moreover, the thyroids of female animals should be examined when estrus does not exist so as to exclude the activating influence of the anterior hypophysis during estrus. The author points out that the manner in which the extracts are prepared may have an influence on their thyrotropic action. He investigated the thyrotropic action of the serum of pregnant women and found that its subcutaneous injection into guinea-pigs produces a noticeable activation of the thyroid of the animals. For comparison he examined the thyroid of a pregnant guinea-pig and found it likewise activated.

Vaccination of Nurslings with BCG.—Adelberg and his associates regard the Calmette method of vaccination one of the most powerful agents for combating tuberculosis. It is particularly indicated in children who are exposed to direct contact with tuberculous persons and in whom, according to their experience, vaccination lowers decisively the incidence of morbidity and mortality from tuberculosis. Isolation of children for a definite period before and after the vaccination was considered desirable, but the inability to carry it out on a large scale did not constitute a reason for denying it to infants and to older children. Clinical and roentgenologic studies of vaccinated children established that tuberculous manifestations among them were rare and that when present they ran a favorable course. Positive skin tuberculous reaction resulting from vaccination appeared on an average of four months after vaccination by mouth, and one and a half months after hypodermic vaccination. The authors urge vaccination of all infants living in contact with tuberculous persons.

Mantoux Reaction in Group Study of Children.—Rakhlina reports her experience with the Mantoux skin test in the Tuberculosis Division of the Institute for Protection of Motherhood and Childhood. The histories of 335 children who gave a positive reaction were followed for a period from 1926 to 1930. The majority of the patients suffered from an active form of tuberculosis. Of these, 95 per cent gave a positive reaction after the first injection. Tuberculous infection can be ruled out in children who do not react to repeated injections in a dilution of 1:100. In the majority of instances the degree of reaction was indicative of the severity of the process. A severe reaction was obtained, as a rule, in mild processes and a weak reaction in grave forms. Children with exudative processes gave a severe reaction. Absence of anergy was rarely observed, usually a few days before death. Local reactions were most frequent in older children with a mild process. Febrile reactions were unusual and did not affect the general health. Evaluation of focal reaction is difficult and calls for much caution. The author concludes that the Mantoux test is a safe procedure and that it is more sensitive than the Pirquet test.

Silicosis in Metal Polishers.—Bellander concludes that danger of silicosis is present in metal polishing especially for workers with defects impairing the pulmonary circulation. The most important preventive measure is the exclusion of such workers from this occupation. While tuberculosis is a grave complication in silicosis, silicosis may have a certain therapeutic effect, possibly marked, on pulmonary tuberculosis, as a slight degree of silicosis probably hastens encapsulation with consequent healing of the tuberculosis or a long latent period.

THE PRESENT STATUS OF IDIOPATHIC ULCERATIVE COLITIS

WITH ESPECIAL REFERENCE TO ETIOLOGY

MOSES PAULSON, M.D.

Associate in Medicine Johns Hopkins University Gastro Enterologist to
the Diagnostic Clinic and Assistant Visiting Physician
of the Johns Hopkins Hospital

BALTIMORE

Any involvement, regional or general, of the large intestine above the lower part of the rectum resulting in a sanguineous, a mucosanguineous, a mucopurulent or a mucopurulent-sanguineous exudate, with or without diarrhea, due to known or unknown factors, save that of a neoplasm, is a colitis. Clinically the corollary follows that a colonic exudate or feces containing blood, mucoblood or pus, or all of them, is due to a colitis when neoplastic disease and perianal perirectal and localized disturbances of the hemorrhoidal area are eliminated as causes.

This communication concerns itself with a form of colitis known as idiopathic, primary, nonspecific, ulcerative chronic ulcerative, hemorrhagic or suppurative colitis colitis gravis ulcerosa or ulcerose.

ETIOLOGIC CONSIDERATIONS

General Prevalence—This syndrome is not restricted to age, sex, season or zone. The greatest number of cases fall within the second, third and fourth decades.

Epidemiology—Idiopathic ulcerative colitis possesses neither epidemic nor infective properties. Its lack of transmissibility is striking. The records of the Johns Hopkins Hospital do not reveal more than one case in a family.

Predisposing Factors So Called—Nothing definite is known in this connection. "Predisposing factors" so called, when associated with ulcerative colitis is a term used to denote the relative concomitance of initial symptoms and exacerbations with other factors. They have been designated as infections of the upper respiratory tract, epidemic diarrhea (in all likelihood bacillary dysentery), or diarrhea following the drinking of polluted water as well as amebic dysentery and so-called factors acting locally by reducing bowel resistance in the form of enemata and laxatives.¹ Similarly the

psychiatric aspects, probably because of the occurrence of ulcerative colitis in some young men and women of psychoneurotic or emotionally unstable tendencies, have come into consideration of late.²

It is my belief that, when some powerful systemic or other agent, as noted, is called in aid or is regarded as of etiologic significance, the intestinal flora or a so-called specific organism cannot be regarded as either a sole or a primary cause of the lesion seen in ulcerative colitis.

Parasitology—The very definition of the syndrome of idiopathic ulcerative colitis precludes the presence of pathogenic parasites. Yet the simultaneous appearance of amebic dysentery and ulcerative colitis has been claimed to occur as distinct entities in some cases by virtue of the concomitant occurrence of three conditions: (1) the isolation of *Endamoeba histolytica*, (2) the feeling that the etiology of ulcerative colitis has been ascertained, and (3) the presence of types of ulceration seen by rectosigmoidoscopy, said to be characteristic for each of these conditions. That these two disturbances may occur simultaneously does not involve the acceptance of the interpretation that has been given, for these reasons. First, the specific etiologic factor in ulcerative colitis—as will be indicated—remains undetermined. Second, rectosigmoidoscopic observations described as characteristic of this disorder are to others,³ including myself, indistinguishable from chronic bacillary dysentery. In consequence, it would seem to be in error to deviate from the accepted teaching, namely that the infection by *E. histolytica* be regarded as primary and the involvement of ulcerative colitis as secondary. Incidentally, those cases in which after adequate treatment the parasite disappears but the colitis persists fall, in my opinion, within this group. This conservative attitude, it is felt, should likewise apply in the conceivable possibility of the engrafting of an amebic dysentery on a preexisting ulcerative colitis when it is impossible for the clinician as it must be in practically all such instances, to determine the priority of disorder. If Craig's complement fixation test for amebiasis should prove to be significant some cases diagnosed as primary ulcerative colitis are those of amebic dysentery or secondary to that disease. This phase of the problem has been brought forth recently by Kieffer.⁴

The presence of other amebas in ulcerative colitis is not particularly significant, since they are not disease

From the Departments of Medicine, Gastrointestinal Clinic and Pathology and Bacteriology of the Johns Hopkins University School of Medicine and Hospital.

Owing to lack of space this article has been abbreviated in THE JOURNAL principally by the omission of general anatomic physiologic and clinical consideration. The complete article appears in the author's reprint.

producing This is true, too, of the flagellates—even though medical literature sometimes may lead one to believe to the contrary—for parasitologists have deduced no satisfactory scientific evidence of pathogenicity There are data to show that *Balantidium coli*—the ciliate—may produce an ulcerative colitis,⁵ but it is not the type with which we are concerned here

Bacteriology—A Uncommon Bacterial Types *B. proteus*, *B. pyocyaneus*, *B. lactis-aerogenes* and *B. mucosus-capsulatus* have been incriminated as etiologic agents in chronic ulcerative colitis.⁶ Actually, no satisfactory evidence has been adduced that any of these organisms bear any essential relation to this condition.^{6a} *B. paratyphosus B* has been isolated on occasion from intestinal lesions in some cases of ulcerative colitis and has therefore been regarded in those instances as a significant factor in etiology

B. Anaerobes There appears in the literature no satisfactory direct evidence for the belief that *B. welchii* is of etiologic significance in ulcerative colitis Felsen's⁸ report of satisfactory clinical responses by intestinal oxygenation does not prove the importance of this bacterium in the etiology of this condition, for he himself suggests that the effect of such therapy may be on intestinal tissue proper Contrarywise, in my studies on ulcerative colitis I have been impressed with the relative fewness of *B. welchii* generally encountered on anaerobic deep blood agar plates made directly from the material of these cases Also, I⁹ have found, in vitro, that fresh noncoagulable blood in normal as well as from ulcerative colitis cases has a deleterious effect on *B. welchii* This might explain why this organism is not found in large numbers and therefore is at present not to be regarded as the cause of the condition

C Virulence Ascribed to Normal Bacterial Inhabitants of the Colon There are some observers who present the idea that, for some unexplainable reason, the local tissue resistance of the colon becomes lowered, and organisms that are habitual saprophytes take on an added virulence and become pathogenic This has been well expressed by Dr T R Brown,¹⁰ chief of the Gastro-Intestinal Clinic at Johns Hopkins Hospital, in the following manner

Is it not possible that the cause of the disease is to be found not in the presence of a definite and specific infective agent, but rather in the absence of some protective substance or mechanism or of something which normally inhibits the bacterial invasion of the intestinal wall, perhaps due to metabolic error, or endocrine disturbance or lack of a specific bacteriophage, or absence of some normal bactericidal substance in the intestinal mucosa?

D B. Coli There is no convincing experimental evidence on record that *B. coli* is of primary significance in the etiology of the process I⁹ have recently deduced suggestive confirmation of this view From experiments in vitro in undiluted blood and in saline-blood dilutions from both normal and ulcerative colitis

cases, this organism is destroyed and its growth inhibited, respectively

E B. Dysenteriae The view that chronic ulcerative colitis is an aberrant form of bacillary dysentery persists in England,³ on the continent,¹¹ in Canada¹ and, possibly to a lesser extent, in this country Ulcerative colitis appears to differ from bacillary dysentery in four particulars First, ulcerative colitis is not known to present the abrupt, brief attack of the ordinary case of bacillary dysentery Second, the age incidences are dissimilar Third, ulcerative colitis is not infective Fourth, in ulcerative colitis, *B. dysenteriae* is not encountered

The first two difficulties are explained principally by Hurst and his co-workers by the hypothesis that ulcerative colitis is a modified form of bacillary dysentery Actually, this may or may not be so, or the contention may be true only of a group of cases which may have begun as bacillary dysentery but which, when investigated, are diagnosed as idiopathic ulcerative colitis because of negative bacteriologic, parasitologic and serologic observations As to the third objection, while ulcerative colitis is noninfective in that almost never are two cases found in the same household, recurring or chronic bacillary dysentery with which it is comparable is regarded in many quarters as being noninfective, too, especially when the offending organism, rarely isolated in this condition, is not to be encountered Fourthly, the bacteriology and serology of ulcerative colitis and that of recurring bacillary dysentery are not as dissimilar as would appear at first glance In ulcerative colitis, *B. dysenteriae* is not to be found In chronic bacillary dysentery these organisms are rarely to be encountered, their paucity, when discovered, and the severity of the disease are such that the causal relationship of these bacteria to the lesion of chronic dysentery is somewhat incredible In ulcerative colitis, the serum agglutination reactions with *B. dysenteriae* are negative, in a majority of definitely established subacute and chronic bacillary dysenteries, Douglas, Colebrook and Morgan¹³ have shown that the serum agglutination reactions are of no diagnostic import Some authorities deny the occurrence of agglutination altogether^{3b} De Lavergne and others¹⁴ demonstrated in Flexner dysentery a relationship between the diminution of agglutination properties and the increase of time elapsing between the onset of the attack and the performing of the agglutination test Incidentally, here it is to be observed that many cases finally diagnosed as chronic ulcerative colitis are studied intensively for the first time years after the initial attack Thus, it is possible that the differences between chronic ulcerative colitis and chronic bacillary dysentery may be quantitative and not qualitative, at least in some cases

Recently, I⁹ learned that in undiluted and in dilutions of noncoagulable human blood (1 cc of blood to 3 cc of saline solution) in normal and bacillary dysentery cases, *B. dysenteriae* Shiga and Flexner failed to survive on incubation at 37 C, in bouillon controls they grew abundantly The experiments suggested that the

continued presence of fresh blood in the intestine might explain, in a measure, the inability to isolate these organisms from many with chronic bacillary dysentery and in some other patients, who in consequence of this as well as of negative parasitologic and agglutination studies are classified as having chronic ulcerative colitis.

Ulcerative colitis and recurring or chronic bacillary dysentery are thought by many to be identical in these respects. The clinical course of the two conditions is indistinguishable. Pathologically, the appearances of the large intestine in bacillary dysentery and ulcerative colitis are not to be differentiated. Chronic bacillary dysentery, like chronic ulcerative colitis, usually involves the distal portions of the large bowel, in exceptional instances in both conditions the lesions appear to be restricted to the more proximal segments.¹⁰ In acute bacillary dysentery, as in ulcerative colitis, the process attacks the mucosa with early rectal involvement.¹⁰ In more than fifty cases of definite acute, subacute and chronic bacillary dysentery in infancy and childhood in which I have performed rectosigmoidoscopy, no normal rectums or sigmoids were seen. In most instances the appearances to me were identical with the appearance of ulcerative colitis. Other observers have reported similarly.⁸ Roentgenograms in both conditions often are not unlike one another. Even many of the complications observed as occurring in ulcerative colitis, such as fibrosis, strictures, polypi, perforation, joint changes, and transient paralyses sometimes involving muscular atrophy, are noted by MacCallum¹⁰ as complications of bacillary dysentery. Buie,¹⁷ who wrote that the rectum and lower sigmoid were characteristic in chronic ulcerative colitis, now states, in speaking of the pathology of this condition, "I am willing to concede that this picture is variable enough to keep me somewhat in doubt as to its various manifestations."

Thorlakson¹² reports that Cadham, by a special technic, from the wards of the Winnipeg General Hospital, in nine isolated instances usually designated as ulcerative colitis, has found *B. dysenteriae* in one fulminating, two subacute and three chronic cases.

From the foregoing data, it appears that ulcerative colitis meets the requirements of a syndrome rather than of an entity. It is a set of symptoms and the sum of signs of a morbid state, the etiology of which is either unknown or, like bronchial asthma, variable. Its clinical course, with its pathologic manifestations, complications and sequelae, are indistinguishable from chronic bacillary dysentery, thus rendering its characteristics not specific for idiopathic ulcerative colitis.

The correlation of idiopathic ulcerative colitis and bacillary dysentery is not to be interpreted as my belief that the etiology of the latter is that of the former. The specific cause of ulcerative colitis remains undetermined and it is my impression that not the same etiologic factor is operative in every case, so that *B. dysenteriae* may have been the primary agents in some cases in which bacteriologic, serologic and parasitologic examinations are negative. The dissimilarities in these two conditions, however slight, do not seem explainable clinically in all cases of idiopathic ulcerative colitis on the basis of its being an aberrant form of bacillary dysentery.

F The Vitamin Theory. Avitaminosis as a cause of ulcerative colitis is not supported by clinical experience. However, experimentally, striking chronic lesions resembling this condition in man, macroscopically and microscopically, have been those produced in animals by the feeding of vitamin deficient diets.¹⁸

G Focal Infection. Here, too, as in many conditions in which the cause is unknown, focal infection has been thought to be of etiologic importance. The relationship remains to be proved both experimentally and clinically. Experimentally, Cook's¹⁹ researches appear inadequate because of the use of primary cultures which may or may not have been pure and the absence of control animal studies with streptococci and other organisms from foci of other types of hemorrhagic or ulcerative colitides. Still other studies²⁰ have been done with mixed cultures and cultures made from tooth and tonsillar foci, the determination of the sole presence of a specific streptococcus being made by morphology alone, a method regarded as unreliable, as will be indicated later. Clinically, there is no evidence of dissemination from a focus to a distant involvement, by a toxin, by positive blood cultures or by associated conditions, as arthritis in which the streptococci found are said to be different from the streptococci in ulcerative colitis.¹ Positive blood cultures are of no significance because of their rarity in spite of the ready access to the blood stream by intestinal organisms because of ulceration.

Obviously, eradication of all sources of infection should be undertaken. However, I have seen no instance in which striking amelioration could be attributed solely to such elimination. Relief thought to be so obtained often may be purely coincidental because of the self limited tendency of the acute phases or possibly of some influence of other associated forms of therapy.

H Vagotonia. Its exact role remains to be determined. Eppinger and Hess²¹ state that "these diarrheas rarely last longer than twenty-four hours." When they do, it is a suggestion that what was purely functional has become an inflammatory disease of the mucosa.

I Calcium Metabolism. Disorders of calcium metabolism with possible tetanic manifestations and changes in capillary permeability, more marked in the intestine have been said to be of some influence in this condition.²²

J Cocci. Diplococci, Pneumococci, Enterococci, Streptococci. A diplococcus may be a pneumococcus, an enterococcus or one of many varieties of streptococci. When observed as young cultures in liquid mediums, when smeared from solid mediums or from material secured directly from the bowel, these organisms—even those streptococci which in older liquid cultures or in subcultures may present characteristic chains—appear as diplococci. Occasionally diplobacilli, diphtheroids, staphylococci and small, plump gram-positive bacilli on direct smear, as well as from early

cultures in liquid mediums, especially when the cultures are mixed, may be indistinguishable from diplococci. Obviously, then, a diplococcus is not distinctive, morphology is not characteristic, it is merely descriptive. The use of terms such as "diplococcus" and "diplostreptococcus" to designate a specific organism is therefore in error, for they denote characteristics common to several types of intestinal streptococci. The attempt, then, to diagnose the presence of any one or more of these organisms on the basis of morphology alone—in smear and culture of intestinal material or in intestinal tissue—is plainly a futile task, as shown in the accompanying illustration. Yet there is published evidence of such occurrences, as will be noted, on which definite deductions have been based with respect to the etiology of ulcerative colitis.

For instance, pneumococci have been said to be etiologically responsible for ulcerative colitis, apparently because diplococcal forms present in feces resembled their morphologically. There is no instance or record in which the reported presence of this organism has been substantiated by adequate identification. Also, Bergen, working under Rosenow and with Rosenow's methods, in presenting, in 1924 and 1925, experimental data on which his entire hypothesis is founded, namely, that a gram-positive diplococcus is the cause of ulcerative colitis, reported seventy-five strains as isolated with only twenty-five studied culturally. In 1927

Examples of nondistinctiveness of the diplococcal arrangement of a variety of strains from ulcerative colitis in Rosenow's dextrose brain broth: A alpha zoned streptococcus B alpha zoned enterococcus C beta hemolytic streptococcus D gamma zoned (non hemolytic) streptococcus E Welch bacilli F, mixed culture of all the foregoing strains

the organism was reported²³ as isolated in 189 of 266 cases, 105 of which were determined culturally. Here, eighty-four strains seem to have been established purely on the basis of morphology. This method of diagnosis is regarded by many bacteriologists as inaccurate, misleading and untenable for reasons just noted.

In 1924 and 1925, the so-called diplococcus was reported by Bergen²⁰ as that of an alpha zoned (J H Brown classification) bacterium, which "never ferments inulin or mannite"²⁴. In 1927, Bergen²⁵ added that of "105 strains tested, 41 fermented mannite and 64

did not". In 1930 he²⁶ reported that the diplococcus "does not usually ferment mannite but lacks the power to ferment inulin".

The first requirement in the establishing of a particular organism as being "etiologically significant" in ulcerative colitis or in any other disease is that the criteria for its identification as set down by its proponent be constant, at least in his own hands. Obviously, this has not been the case. That cocci morphologically identical but culturally different—more than one type of coccus—have been dealt with, a contention that I²⁰ have maintained for years, is evidenced by these changes in characteristics originally given as constant and as differentiating them from similar organisms. On the other hand, there is no proof that these alterations, encountered presumably under identical conditions, are variations of the same bacterium.

Organisms presenting these characteristics have been isolated by me from normal human feces by a technique described elsewhere, from ulcerative colitis and in rarely encountered acute and subacute amebic dysentery cases. The presence of such bacteria in chronic bacillary dysentery is now being investigated.

Thus, intestinal lesions produced in animals by the intravenous injection of more than one type of streptococcus, as well as similar but more marked lesions secured on the administration of mixed cultures, obviously cannot be accepted as experimental proof of the specificity or of the significance of a definite organism in the etiology of this condition. Incidentally, etiologic specificity itself has been urged by attempted descriptions of a particular organism, the desire to establish the condition as an entity, and especially by the use of such terms as "definite causative microorganism," "specific vaccine" and "specific serum".

Inadequate control studies, as has been pointed out in detail elsewhere,²⁸ in addition to the absence of essential control data, as the isolation and the response of laboratory animals on administration of streptococci and other organisms from other types of ulcerating or hemorrhagic colitides, is a further bar to the acceptance of such contentions. Suffice it to say that a perusal of the literature does not indicate a single study, adequately controlled, confirming a specific organism as the cause of this condition, nor am I able to determine from such sources which streptococcus can be regarded as of etiologic or secondary significance, since the criteria have varied from time to time, indicating a variety of streptococci involved.

In thirteen of fourteen cases of acute exacerbations of chronic ulcerative colitis, I²⁷ isolated ten types of streptococci, including the "diplococcus" meeting Bergen's original criteria. No one type was found to be present in more than three cases, the so-called diplococcus being isolated in two cases, in one of which it predominated. Five of seven varieties of alpha zoned streptococci intravenously injected into rabbits, including the organism originally referred to by Bergen, produced lesions, confirmed by microscopic sections, primarily in the lower colons and rectums of 45.5 per cent of the animals. A rectal and a colonic involve-

ment was noted in one of six rabbits intravenously injected with the so-called diplococcus. A heated (killed) culture of a beta hemolytic streptococcus (foreign protein) isolated from the uterus of one with puerperal sepsis, *B. coli* from a normal human sigmoid and in a case of amebic dysentery, and *B. dysenteriae* Shiga and Fleisner produced lesions, confirmed by microscopic section similar in pathology and location to those just referred to in a large number of rabbits. In short, this research shows the variety of streptococci to be found in cases of ulcerative colitis and the production of lesions identical in pathologic changes and similar in location produced by several of them as well as by organisms from other sources. A subsequent study,²⁹ tending further to establish this nonspecificity of bacterial influences in the etiology of ulcerative colitis, showed another strain of streptococcus not previously encountered as producing lesions—proved by microscopic section—in the intestine of four of six animals. In addition, *B. lactis-aerogenes* and *B. coli* and foreign protein (sterile dextrose brain broth) produced diarrhea in some instances. Later, Buttrick and Sevin³⁰ demonstrated that still another streptococcus isolated from ulcerative colitis produced colonic lesions in rabbits, which roentgenologically were similar to those sometimes seen in man with ulcerative colitis.

At this time it appears that of possible bacterial factors in the etiology of ulcerative colitis, streptococci and enterococci, normal inhabitants of the intestine, are the most significant as secondary phenomena, not by reason of animal experimentation, which, as noted, remains inconclusive, but because of the following:

1 Recent studies⁹ have shown that when fecal emulsions are grown in vitro in human noncoagulable blood in normal and ulcerative colitis cases, by a simple technique intended to stimulate continued bleeding, only streptococci and enterococci survive. In infusion bouillon controls, gram-negative bacilli predominate. Under identical conditions in diluted blood (1 cc of blood to 3 cc of saline solution) other organisms lived but not as numerous as in bouillon, resulting in a quantitative diminution of flora and a relative increase, when not absolute, of cocci because of the greater ability of the latter bacteria to live in blood than of the other intestinal bacteria, which are destroyed or inhibited by the bacteriocidal and bacteriostatic properties of this tissue.

From this research, the following deductions have been made. This diminution of flora noted in ulcerative colitis and in the few severe amebic dysentery cases seen in Baltimore, as well as the relative increase of cocci in many cases of the former (the bacteriology of amebic dysentery has not been studied in this connection), is due, in part if not completely, to the presence of blood which appears to act, generally speaking, less deleteriously on cocci than on other organisms of the intestinal flora. Thus the greater and more prolonged the intestinal bleeding, regardless of cause, the more marked changes of the nature described appear likely to occur. The presence of blood, then, favoring the growth of cocci normally present, may result in their becoming pathogenic and continuing the process,³¹ espe-

cially since Todd³² has demonstrated that the passage of streptococci through serum alone in many instances will reestablish virulence. It is thought also—in view of this research—that other organisms, normally present in the intestine, surviving in this abnormal medium, may assist to a lesser degree in carrying on the involvement. If the production of colonic lesions in animals by intestinal bacteria is of import, then further support for this belief is to be had in the fact that more profound lesions are to be encountered with mixed than with pure cultures.²⁷

2 Streptococci indistinguishable culturally from those described as being found in ulcerative colitis have been isolated from normal stools by Dukes³³ and by myself⁹ by the use of blood as a medium, the details of which are described elsewhere, in which streptococci multiply and other organisms are destroyed or inhibited. Pathogenicity, then, ascribed to such bacteria or any other organisms normally present, presupposes a preceding or primary factor responsible in some measure for this altered characteristic. Such normal presence precludes considering them in the same light as *Endamoeba histolytica* and the typhoid-paratyphoid-dysentery group not normally encountered, and primary causative agents of dysentery.

3 Streptococci in ulcerative colitis, in my experience, usually are not in actual predominance but may be relatively increased. If they were primary agents, an absolute increase on direct blood agar plates would be expected. Intricate cultivation methods and the difficulties in isolation, even with the use of a selective medium for streptococci, as Rosenow's dextrose brain broth, further indicate this lack of preponderance. Such predominance alone in Rosenow's dextrose brain broth is of no significance because it is a selective medium.

4 Logan's effort showing that "sterilizing the colon has not resulted in healing the ulceration" indicates the presence of other factors in the etiology of this condition.

PROGNOSIS

It has been the experience of the gastro-intestinal group at the Johns Hopkins Hospital that, if sufficient time is allowed, recurrences are virtually certain to occur in all but the exceptional cases. The possibility of permanent cure is remote in any type of true ulcerative colitis at the present writing. The acute fulminating severe cases present a high mortality regardless of the method of treatment. However, it is surprising how long some patients can live even when local and general symptoms are marked.

TREATMENT

Idiopathic ulcerative colitis primarily is a medical problem, every case first should have the benefit of thorough medical treatment. While most of the milder cases, in my hands, are well controlled by dietetic and pharmacotherapeutic measures, usually without polyvalent vaccine or serum, the management of the severer ones is discouraging, in that apparent relief, regardless of the concomitant therapeutic agents used, is followed by relapse, if they are observed long enough.

Unfortunately there is no "specific" therapy in this disorder. Therapy, in this condition, to be regarded as specific—in the light of prevailing knowledge—

should meet the following criteria. First, the product should be prepared from the causative organism, this, as has been indicated at length, remains to be determined. Second, the response on its administration should be abrupt, marked, complete, without remissions or intermissions and recurrences, the facts are that the response, not unlike that to foreign protein therapy, is, when it occurs, relatively slow, and that permanent cessation, save possibly in an isolated instance, remains to be established. Third, the attainment of a "cure" should be susceptible of accomplishment only with the "specific" therapeutic agent and none other, yet other measures have been used simultaneously with such "specific" agents, while transfusions alone, as well as preparations other than those said to be specific, have accomplished, frequently, similar results.

Numerous observers have reported "good results" on the use of mixed autogenous vaccines and of those either of enterococci dysentery or colon bacilli.³⁴ Bargen,³⁴ who in 1927, on "specific" vaccine administration, reported markedly satisfactory responses in 153 of 200 cases (77.5 per cent), the majority of which presented severe manifestations of ulcerative colitis, stated in 1929 that specific serum so called was being used, since results with "specific vaccine" in severe cases were unsatisfactory.³⁵ Of seven patients receiving adequate amounts of this serum, two died and two were clinically well. Later,³⁶ twenty-four of fifty patients were reported as symptom free. However, rectosigmoidoscopy often reveals little objective improvement in many who appear well. In view of these facts, as well as of the knowledge of the self limitation of exacerbations and of the recurring characteristics of this condition, it will be necessary to wait at least five years before his later reported benefits with serum can be properly evaluated objectively as well as subjectively. Remissions have been known to occur on mere bed rest alone. Recently Kalk³⁷ reported startling relief on both the intramuscular and the intravenous injections of ordinary horse serum in some ulcerative colitis cases. Hurst, Crohn, Bell, Boehnke, and Korlsch and Gross (the last named state that they have reports of nine others showing similar experiences) have in recent years reported striking remissions or intermissions by the intravenous injection of polyvalent antidysenteric serums.³⁸ However, this has not been the experience of Tidy and Watson.³⁹ T. R. Brown and I have felt on occasion that in some cases there was more than a coincidental relationship between the administration of polyvalent antipneumococcus serum and the relief secured. Incidentally, it is believed that the serum made by Mulford-Sharp and Dohme for use in ulcerative colitis cases is a polyvalent streptococcus serum, since in our hands the organisms sent by Bargen and used by them in its preparation represent more than one distinct strain of streptococci.

Of late, transfusions alone⁴⁰ have been used with marked success in many cases, but already there have

been some recurrences. The marked improvement said to be noted roentgenologically on the administration of "specific" serum and vaccine has been reported when blood transfusions alone⁴⁰ or horse serum is used.⁴¹ Bacteriophage has been used in isolated cases⁴² and calcium and paratyphoid therapy have been reported as beneficial.⁴³

In short, the medical management consists of rest, psychotherapy, diet, drugs, vaccines, serums, irrigations and instillations (although irrigations and instillations are not recommended), all of which have been detailed in the articles to which references have been made here. In ulcerative colitis it is felt that any procedures offering the slightest possibility of relief may be justifiably used.

As for surgery, it is believed that ileostomy should be the operation of choice because it puts the colon to rest, and that it should take place somewhat earlier than is practiced, "before ulcerations have become too deep, the disease very extensive, general resistance lowered and metastatic involvement of other organs and tissues have brought about irreparable damage."⁴⁴

SUMMARY

1 Chronic ulcerative colitis is a syndrome, for it presents a fairly constant set of symptoms and signs possibly of variable but of no demonstrable specific etiology. It involves the large intestine, particularly its distal segments, and resembles chronic bacillary dysentery clinically, pathologically, roentgenologically, and in some respects bacteriologically and serologically. However, the exact relationship between B. dysenteriae and this condition must remain *sub judice*.

2 (a) Avitaminosis as a cause of ulcerative colitis is not supported by clinical experience, although the experimental evidence is striking.

(b) Vagotonia as well as disturbances of calcium metabolism, has been thought to play a role in etiology.

(c) There is neither satisfactory direct evidence nor properly controlled confirmatory studies establishing a specific or primary etiologic association between any bacterium and chronic ulcerative colitis.

(d) The definite connection between foci of infection and the etiology of this condition remains to be proved both experimentally and clinically.

(e) Experimental data indicate the nonspecificity of bacterial influences in this disorder.

(f) Recent work suggests that the greater and more prolonged the bleeding, regardless of cause, the greater will be the diminution of the flora and the more marked the relative increase in cocci. These cocci, and to a lesser extent the other surviving intestinal organisms normally present, probably are responsible for a secondary infection.

3 Recurrences at present are certain to occur in all but the exceptional cases. The possibility of permanent cure is remote.

4 There is no specific therapy, since the specific etiologic factor, if there is any, remains to be determined and the therapeutic response is not specific. Ileostomy is regarded as the operation of choice and should take place earlier than is practiced usually.

ABSTRACT OF DISCUSSION

DR SARA M JORDAN, Boston There are two aspects of ulcerative colitis which are worthy of further elaboration. First, it has an acute phase which suggests an acute infectious process for which I hope there is a definite, specific agent which can be treated and for which help may be hoped for from vaccines. Second, it has the phase of chronicity and of periodic remissions, which make me feel in sympathy with the suggestion offered by Dr Thomas Brown at the last meeting of the Gastro-Enterological Association, in Washington, when he asked the question: Is it not possible that there is no definite, specific organism responsible for this disease but that it is due to the absence of some defense mechanism or some defense organism which prevents the infection of the intestine by the normal inhabitants of the intestine? These two aspects of the disease make both of these theories a possibility. One of my associates, Dr Kiefer made a study of thirty or forty cases in which he has tested the blood of patients with ulcerative colitis and found in 74 per cent that the Craig test for *Endamoeba histolytica* was positive, and in many of these cases antiamebic treatment gave what was thought to be favorable results. In the treatment of this disease, therefore, the possibility is considered of an association of *Endamoeba histolytica*, and secondary ulcerative colitis, and I feel that it is sometimes well to use antiamebic treatment in ulcerative colitis. Dr Paulson mentioned that ileostomy must be done early enough. One must not operate too early. It is a very serious problem to decide when an ileostomy should be done. One must take into consideration not only the fact that ileostomy is an unpleasant condition but that it is a permanent condition. In my experience an ileostomy cannot be taken down. The colon does not regenerate. The acute septic symptoms are undoubtedly relieved and a patient who otherwise might die lives, but his colon does not heal. Therefore one has to be guided by good clinical judgment and perhaps also by a bit of good fortune in deciding which cases should have ileostomy and which should not.

DR FRANK SMITHIES, Chicago During the past decade attention has been called to four major types of colitis associated with ulcerative lesions: (1) the prevalence of amebic lesions, (2) the presence of chronic ulcerative colitis, "idiopathic or regional ulcerative colitis" (by Bagen), (3) tuberculous ulcerative colitis, and (4) the type of colitis emphasized by Crohn, in which one deals with definite infective processes localized at the terminal ileum and cecum. I have maintained that in "Bagen's syndrome" one is dealing with a fairly localized infectious ulcerative disease of the colon which infection is secondary to an infectious ailment somewhere else after the fashion perhaps, of widespread metastases occurring in malignant disease. I consider that chronic ulcerative colitis of Bagen's type is a local evidence of a systemic infection carried from somewhere else by lymph and by the venous blood streams. Study of early cases gives clues to the process of ulcer production: these early lesions exist as infectious thrombi of minute blood capillaries; in the secondary stage these coalesce as early, primary, multiple petechial lesions, and, in the third stage, systemic-borne infection of these areas occurs and ulcer production follows. It is the study of only well established instances of this localized infectious ulcerative colitis that accounts for the failure to appreciate the causative mechanism and to neglect consideration of the underlying vascular anomalies that readily facilitate local stagnation and the persistent presence of bacteria conveyed to the region from far distant foci. Such distant foci are about the head, the teeth, the endocardium, the biliary tract and probably the wall of the bowel itself (either primarily from stagnant bowel contents or blood and lymph borne). Therefore in addition to local treatment of the bowel lesions the proper therapy consists in the location and eradication of primary foci of infection, measures to combat the systemic damage caused by that infection and general supporting treatment. In my experience transfusions of whole blood freely given, have proved of greater value than specific vaccines or their derivatives.

DR FRANK H LAHEY, Boston I am prompted to say a few words about the surgical treatment of this lesion because it is a serious lesion and because often the question of life hangs on a narrow balance. There are a certain few things

that my associates and I have learned in approximately forty of these cases which are of value. One is that ileostomy must be of the transverse type rather than of a lateral type in order that the course of the fecal stream may be completely sidetracked. Next the decision must be made, if one is in doubt on the early side. We have definitely lost patients by delay. Finally, one must realize when these patients are operated on that this colon must be handled like a hot coal, because its walls harbor organisms. The vessels close to the mesentery are lined and filled with septic thrombi, which readily become septic emboli. Manipulation produces distant infection and local peritonitis, therefore, surgeons should realize that these patients should be operated on under local or spinal anesthesia. The ileum should be hooked up, pulled out, implanted and cut across, and the less done, the better. In a majority of these cases ileostomy does not cure ulcerative colitis. When they reach the stage in which an ileostomy is needed, multiple destructive lesions in the colon have left strictures, fibroses and narrowing, and in many of the cases even after a temporary relief from ileostomy there has been a discharge of blood and pus that we have succeeded in curing ultimately only by colectomy. When these patients have a return of symptoms after an ileostomy, they can be relieved of these symptoms by complete colectomy in stages.

DR M H STREICHER, Chicago The one point I agree on with Dr Paulson is that there is no specificity in any organism. I agree with Dr Buie and Dr Bagen that there are definitely four stages which one can differentiate. If one sees enough material one will differentiate the various stages without difficulty. Since 1926 I have observed 220 cases. The diplostreptococcus of Bagen is not specific but is of primary importance. I have had vaccines made of several types and in the cases in which the Bagen diplostreptococcus was left out the patients did not get along as well. That is the best criterion that I have. The vaccine that I have made up is a mixed polyvalent bacterial vaccine. This is the best that can be done at the present time. This vaccine includes the Bagen diplostreptococcus in addition to other bacteria. I want to refer to what Dr Lahey and Dr Jordan said about surgery. In all the operative cases that I have seen, including the three colostomies that I have done, I have nothing but criticism to offer. Surgery in ulcerative colitis is cruelty.

DR JOHN L JELKS, Memphis, Tenn. This is interesting to a man who looks into one or more colons every day. He hasn't found any of these diplococci of Bagen. He has seen a good many cases so diagnosed. He has treated cases that had been treated for the Bagen bacillus for a year, the colons were badly ulcerated and filled with *Amoeba histolytica*. He has seen cases treated thus that presented suppurative tonsillitis filled with pus, and pyorrhea. In the chapter on protozoa in man in Sajous's *Cyclopedia of Practice of Medicine*, I am referring to the fact that I am finding some important factors in productivity in these cases. I am referring to spirillae and recommending that oral sepsis and accessory sinuses should never be omitted, whether the case is amebic or not amebic. There are many streptococcal colitis cases which have not been so diagnosed but were called chronic ulcerative colitis, spastic colitis, spastic diarrhea, or mucous diarrhea. In the treatment of these cases it has been well said that one should be careful not to operate too soon as well as to do it soon enough. I prefer the transduodenal irrigation in these cases, with a proper diet and proper colonic irrigations.

DR L A BLUE, Rochester, Minn. Some of the statements that have been made here have been erroneous and I feel that it is necessary for me to defend one of the most valuable forms of treatment in the care of patients with ulcerative colitis, be it specific chronic, amebic bacillary or what not. My experience has been that the treatment with serum prepared from the Bagen organism has been curing patients. The records of those patients are far better than the records of patients treated years ago by the medical management referred to by those who are still in doubt. When patients are in desperate condition with a destructive disease cannot former experience with an inferior method be accepted as a control to determine that a later method is superior even if such a procedure might not be accepted in a laboratory as a controlled experiment. In this day of enlightenment are we to take patient A and treat him

with a curative serum, and patient B and treat him with something that we know is not going to cure him, in order to satisfy the requirement of some skeptics for control experiments? Is that being done in the practice of medicine today? I am glad that it is not necessary to rely on the bacteriologist for a diagnosis of chronic ulcerative colitis. I am profoundly grateful for the good old fashioned doctor who can call ulcerative colitis a disease instead of a syndrome.

Dr. MORRIS PAULSON, Baltimore. Every statement that I have made here today is based on clinical experience and research as well as on the work of others to which references have been made in the paper. Etiology and therapy should not be confounded clinically. In most disorders they present separate clinical problems. For instance, in duodenal ulcer little or nothing is known of its cause, yet management in the majority of cases by any one of several means is regarded as rather satisfactory. The converse also is true: the cause of a condition may be generally agreed on, yet treatment may be of no avail, as in bacterial endocarditis. In ulcerative colitis no deductions with respect to a specific etiology can be drawn on the basis of reported promising responses by therapeutic agents said to contain a specific etiologic factor, for the reasons already outlined in this paper, particularly under the heading of therapy. As far as the reported successful treatment of ulcerative colitis at Rochester is concerned it is my impression that it is due more to what is known as the successful application of the art of medicine rather than to any particular therapeutic procedure.

ORIGINAL FEATURES OF ARTHROPLASTY OF THE HIP AND KNEE

FRED H. ALBEE, MD, ScD, LL.D.
Professor of Orthopedic Surgery, Columbia University
NEW YORK

With regard to the wisdom of mobilizing ankylosed hips one finds considerable difference of opinion among the best of surgeons. Henderson, reviewing the end-results of arthroplasties of the jaw, elbow, knee and hip, found those for the hip the poorest. Murphy, on the other hand, found that the hip gave him the best results. The problem is obviously more complicated in weight-bearing joints. The occupation and social

Fig. 1—Diagram illustrating erection of bone muscle lever at the hip to prevent dislocation and restore power of abduction and weight bearing.

Fig. 2—Diagram showing result after healing with adequate trochanter leverage.

status of the patient, as well as his temperament, are often determining factors in deciding whether or not to operate. When the hip and knee on the same side are both ankylosed, the advantages of arthroplasty are much increased.

It must always be remembered that stability is very important in the hip, and, although the rotary nature

of the joint lends itself to arthroplasty, unfortunate results have followed arthroplasty when stability was not obtained.

Arthroplasty in cases of tuberculosis should be approached with a great deal of conservatism and only when the roentgenogram shows evidence of complete disappearance of all disease and a complete homogeneity of bone structure throughout the operative field.

Murphy in 1904 reported his technic for arthroplasty of the hip and in 1906 Hoffa¹ reported five arthro-

Fig. 3—Postoperative result of arthroplasty of hip previously arthrodese for tuberculosis by two tibial grafts, stumps of which can be seen purposely left long to increase power of abduction and weight bearing.

plasties of the hip (three by Rochet and two by Nelaton²). From that time on, an increasing number are found in the literature. In fact, in my practice, arthroplasty has become so dependable and well regarded that whenever doing an operation to arthrodese a joint, if that case is a possible favorable case for future arthroplasty, I so plan my arthrodese operation as to make it possible for the future operation to mobilize. At the hip, tibial grafts are preferable because of their possible adequacy of length and strength, thus making it unnecessary to incorporate them in the joint itself. Too, I prefer to take bone elsewhere rather than to disturb unduly periarticular structures or surrounding muscles by obtaining the bone graft material locally. At the knee, for the same reason, I no longer employ the patella as a source of arthrodese material. After its diseased portion has been removed, the patella is left as intact as possible.

To be classed as a good result in the arthroplasty of the hip, there should be a minimum amount of voluntary flexion of at least 25 degrees. Everything being considered, a hip that possesses 25 degrees of painless active motion is far superior to a stiff hip. The joint must be painless and stable in weight bearing. Not only should the hip joint have motion to allow proper sitting but it should function in locomotion as well as in bearing the weight of the body. It is far better to have a stiff immobile hip than a usable one accompanied by weakness, and Baer goes on to say that "the more nearly the joint is similar in size and shape to the original joint the greater will be the stability. Hence arthroplasty is not a resection!" This statement may be true, but one frequently sees excellent functioning

hip joints when there has been an extensive destruction of bone and no semblance of a ball and socket joint remaining. The reason for this is that the muscle control is the all important consideration as to whether a hip is stable and whether there is a satisfactory amount of active motion and weight bearing.

To resolve the mechanics of the hip into simple terms, the hip joint itself is a fulcrum point situated at the end of a lever, namely, the neck of the femur, the distal end of which, or the great trochanter, is controlled by means of powerful muscles that are able, because of this mechanical setup, to pull the thigh into abduction, which is a most important feature of locomotion in that it has very materially to do with proper weight bearing. It is impossible for an individual to bear weight on a limb when the hip is mobile unless the muscle control is such that the limb can be held so that it will not swing into adduction. This is brought about by the mechanical action of the abductor muscles of the hip pulling on the distal end of the lever, namely, the neck of the femur.

If this statement, used as a premise, is true and if it is possible to maintain this muscular control, then the careful modeling with the head of the femur fully filling a deep new-made acetabulum with the difficulty of securing a free range of motion incidental thereto is not necessary or desirable. The deeper the new acetabulum is made with the corresponding femoral head, the greater the task of securing a good range of motion. Therefore, in selecting cases for arthroplasties of the hip, one should be sure that the muscles about the hip are reasonably preserved. Formerly it was my practice to rule out cases in which there had been extensive shortening of the neck of the femur, either from bone destruction or from a telescoping of the head and neck of the femur into the pelvis, for the

Fig 4—Range of flexion obtained in case shown in figure 3

reason that even if the abductor muscles were intact one could never expect satisfactory function of active abduction because the femoral neck lever would still be further shortened by the modeling of the new-formed hip at operation. This was fully realized in designing my reconstruction arthroplasty for ununited fractures of the hip with removal of the head of the femur and because of this the leverage action of the neck of the femur that was lost was restored by length-

ening the lever on the outer side of the long axis of the shaft of the femur by erecting, laterally and obliquely to the shaft, a bone muscle lever with the insertion of the hip abductors to its upper end undisturbed.

In this way one is able, even in the complete absence of the head and neck of the femur, with the denuded trochanter placed in the acetabulum, to establish a lever

Fig 5—Result of erecting bone muscle lever

equally long and nearly as efficient as the normal neck of the femur, with the normal hip joint intact. Mechanical conditions brought about in this manner not only restore abduction with the weight-bearing function of the hip but also prevent dislocation, because as the limb approximates the midline the danger of dislocation where the acetabulum is shallow increases. It should also be realized that it is true that as the limb seeks the midline the erected bone graft lever, already described, travels farther and farther away from the rim of the acetabulum and the side of the pelvis and thus not only puts an increasing tension on the short abductor muscles but also on the surrounding fascial structures, thus holding the head of the femur in the acetabulum and preventing dislocation.

In recent years the destruction of the head and neck of the femur (with telescoping) has not been a deterrent influence to me in selecting such a case for arthroplasty, in that I have found in doing an arthroplasty that a hip joint could be modeled with the head of the femur much smaller than the acetabulum, with sufficient fascia and fat to fill in the interspaces, and that the mechanical influences brought about by the provision of leverage action for muscle control on the outer side of the trochanter not only prevented dislocation but allowed active abduction and satisfactory weight bearing.

TECHNIC

The patient should be placed on a fracture orthopedic table. The Sprengel-Smith-Petersen incision affords such satisfactory exposure that it is the incision of choice for all intra-articular operations, including arthroplasties of the hip. The incision begins at a point about 4 inches below the anterior-superior iliac

spine and is carried along the outer border of the sartorius muscle, upward to the anterior spine and thence backward, following the iliac crest. The gluteal muscles are detached and reflected subperiosteally from the wing of the ilium downward *en masse*, thus giving a wide exposure of the hip joint.

By means of a large carver's or Murphy's gouge, the femur is separated from the pelvis, care being taken to make the bone incision in such a way that a rounded femoral head and a corresponding acetabular cavity are shaped. The acetabulum is not shaped nearly as deep as it formerly was because of the fact that I find that my technic obviates the danger of dislocation, and I further find that this is a very satisfactory influence in bringing about a greater degree of ultimate motion. I have found the various carver's gouges and chisels of great service in my plastic bone work, especially in arthroplasties. The large variety of cutting edges and curvatures of the chisel or gouge shafts enables the surgeon to select the proper tool for almost any emergency.

After the general contours of the joint are thus blocked out, the surfaces are merely smoothed and transformed into regular convex and concave surfaces by means of my arthroplastic hip rasps. The smoothness of these joint surfaces is most important, and therefore the work should be done carefully. The concave and convex rasps are placed in between the femoral head and the acetabulum and these surfaces smoothed and shaped by a to-and-fro motion of the

handle in the manner of a spoke of a wheel. The tools will execute this work faster if an assistant pushes upward on the patient's knee. These instruments enable the surgeon to shape accurately the inner portion of the joint which cannot be seen or gotten at by any ordinary instrument.

The next step is to apply traction to the limb, to separate the head from the acetabulum, so that the bone particles can be washed out by means of a glass cannula connected with a fountain of saline solution over the table, and to allow the

Fig 6—Diagram showing author's approach by turning upward patella and attached tendons with tubercle of tibia. The patella and tendons are restored by sliding dovetailed block of bone into place from side.

easy insertion of the fascial flap, about to be obtained from the thigh, lower down. A semicircular skin incision is made on the outer side of the thigh, midway between the wound and the knee, and a quadrilateral piece of fascia lata with as much fat as is obtainable and about 4 inches long by $3\frac{1}{2}$ wide (in adults) is secured. The subcutaneous layer of fat is divided in equal halves—one half being left attached to the skin and the other half to the graft, which is subsequently to be removed. With a small curved needle, stay

sutures are placed in what are to be the two inner corners, and the fascial graft is drawn in and pushed into the inner confines of the new joint by some instrument as far as possible between the new joint surfaces. Additional sutures are then placed about the periphery of the graft. The fascia is carefully approximated by a continuous suture of number 1 chromic catgut.

If at this point it is thought that the leverage action of the neck of the femur is not sufficient, a bone frag-

ment, consisting of the tip and the outer surface of the trochanter of a varying length approximating 3 inches, is removed with the thin osteotome (figs 1 and 2), with the insertion of the abductor muscles intact, and swung outward from the shaft of the femur from 15 to 20 degrees, by producing a greenstick fracture at its lower end. Cancellous and fragments of cortical bone are then placed in the angulation between the remaining shaft of the femur and the bone fragment. The skin is closed by plain catgut number 0. Dressings and stickers to the thigh are applied. With the limb in moderate abduction, a plaster-of-paris spica is applied for three weeks, from above

Fig 7—Postoperative result of arthroplasty of knee showing V shape of new formed joint for purposes of stabilization.

the opposite side to the toes, with stickers coming out through the plaster, above the ankle. From 15 to 20 pounds of traction with pulley and weight is maintained for three weeks after the removal of the plaster spica, or until a Taylor traction brace or Thomas knee-brace is applied, and locomotion with crutches is allowed.

This brace should be continued for at least three months before weight bearing is permitted, during which time daily massage and active and passive motion are carried out. Traction is most necessary and should be applied before the patient comes out from under the influence of the anesthetic, because of the devitalization and crushing effect that would otherwise be produced on the fascial graft by the involuntary contraction of the powerful thigh muscles. I have found that with a pulley and rope erected over the bed, fastened to a sling beneath the knee, the patient is able to help very materially in mobilizing the joint by pulling the hip into flexion (figs 3, 4 and 5).

ARTHROPLASTY AT THE KNEE

To the patient with bony ankylosis of the knee, a functioning joint with adequate mobility and stability is his object in seeking an arthroplastic operation, even more than at the hip. Whether or not the surgeon follows anatomic contours in modeling the new joint does not interest him, so long as the joint functions. It has been found by Allison and Brooks that it is absolutely impossible to duplicate experimentally, or in

surgically constructed joints at the knee, the normal gliding of the articular bone surfaces. This being true, and as attempts to approximate the contour of the normal joint are so often followed by lateral instability, consisting of lateral buckling due either to capsular laxity or to side slipping of one joint surface on the other because of irregular wearing of joint surfaces, in 1920 I devised a technic,³ based on well known mechanical principles, which ignores the normal contours of the joint and provides both mobility and stability. It has given excellent results.

In separating the tibia from the femur and in the bone modeling, wide V-shaped incisions replace the usual attempts to follow normal bony contours when viewed anteriorly. The convex wedge-shaped plane surfaces of the femur fit accurately into the concave wedge-shaped plane surfaces of the tibia. Weight bearing forces the apex of the wedge-shaped end of the femur so firmly into the tibia that the danger of lateral instability is practically eliminated, and a definitely improved prognosis is afforded.

Up to nine years ago, my own attitude concerning arthroplasty to produce mobility in bony ankylosed knees was one of great conservatism, both because of personal experience and because of observations which I had made on results of others. Either these patients had insufficient motion to satisfy them or, more often, the degree of mobility was satisfactory but lateral instability was present and proved so troublesome as to offset the advantages of mobility.

THE POSITION OF ANKYLOSIS

Extreme flexion is unfavorable to arthroplasty because it makes the technic very difficult and necessitates extensive removal of bone and the sacrifice of that portion of the tibia and femur which has the largest diameter, thus tending to produce lateral instability. If the knee is markedly flexed, it is advisable to perform a preliminary supracondylar osteotomy.

Five years ago I would have said that ankylosis in extension was best left alone but in view of the constantly improving results from arthroplasty I believe that the patient should be given the benefit of the latter unless there are definite contraindications.

The condition of neighboring joints should also be considered. If both knees are ankylosed, arthroplasty on one is definitely indicated, or, if the knee and hip on the same side are ankylosed, there should be slight reason for hesitation.

To women, the awkwardness of ankylosis is more annoying than to men and in young women ankylosis often proves a distinct handicap socially. For both men and women the nature of their profession or occupation will often determine how essential mobility of the knee is to them.

In few operations is the absolute cooperation of the patient so essential as in arthroplasty. However perfectly the technic may be executed a good functional result cannot be obtained unless the patient submits with patience, courage and intelligence to the long postoperative treatment which is likely to be slightly painful in the first stages and is always tedious. It is wise to test the patient's nervous stability by telling him this in advance and to let his reaction to such a statement be an indication for or against the operation.

All persons of weak will or of excessive nervous instability and those who have a litigation interest in

not getting better, such as certain compensation and accident cases, must be eliminated if the surgeon does not wish to risk unnecessary failures.

AGE AND SEX

Age and sex are not vital factors, although patients under 18 years are sometimes difficult to manage after operation, the operation should never be done on young children, and patients over 50 have not the same degree of resistance. It has been stated by some authors that men are more favorable subjects than women, but this has not been my experience.

TECHNIC OF CHOICE

A tourniquet is applied well up on the thigh, so as to allow postoperative application of plaster of paris before the tourniquet is removed.

The knee is approached by a U-shaped incision in the skin and soft parts from the inner and outer aspects downward to just below the tubercle of the tibia. The concavity is upward. This U incision gives the surgeon absolute uninterrupted access to all the parts involved in the formation of the new joint and is therefore distinctly superior to the lateral approach. Also it does not interfere with the important extensor apparatus above the knee, as is likely to happen with the inverted U incision or lateral approach.

The technic of arthroplasty should be so designed as to allow passive and active motion at the earliest possible moment without danger of separation of important structures. As the free gliding of the soft structures or "extensor apparatus" just above the knee joint is absolutely essential to free motion and active control, the severing and resuture of these structures, as in the inverted U incision, are to be avoided, for, if they are severed, not only is there danger of union being insufficient when one wishes to start exercises and passive motion as early as two weeks after operation but because of the cross section severance, there is danger of adhesions at this point between the gliding intramuscular and tendinous tissues. These considerations lead me to choose an incision that does not section or traumatize these soft structures above the knee and to turn the patella upward rather than downward, as advocated by some.

When the knee is being opened up, care should be taken to leave the skin flap overlying the interior work as thick as possible so that the skin and line of suture will not break down following the operation.

Before the patella is turned upward, the ligamentum patellae is detached with a generous amount of bone from the region of the tibial tuberosity, and including it in the dovetail manner indicated in figure 6. First, two holes for later insertion of kangaroo tendon are drilled, one through the tibial tuberosity and one slightly posterior to it. Then, by means of the motor saw and small drill the tubercle of the tibia is removed with the ligamentum patellae and the patella is turned upward. This bone plastic work is done very rapidly with the motor saw and because of the dovetail mortise conformation and the rapid union of closely fitted broad bone surfaces to bone surfaces the surgeon need not question the detachment of the ligamentum patellae—a question that has been raised by MacAusland who considers it inadvisable to sever or disturb the patellar tendon or its attachment. It is distinctly preferable to detach this tendon, as trying to work around it involves unnecessary trauma to neighboring tissue, slows up the operation and limits access to the joint.

It is well known that bone unites to bone more readily and more firmly than tendon to tendon or fascia to fascia. My method of detaching the ligament takes advantage of this, the dovetail mortise conformation being a further assurance of prompt union and of the prevention against the pulling away of the tendon from the tibia even when bony union has not taken place. Also, prompt union obviates delay in the application of postoperative physical therapy, which should follow within two weeks after the arthroplasty. In marked contrast to this is the union of a severed tendon to tendon, which is both slow and unreliable.

After the ligamentum patellae has been thus detached, the soft tissue and capsule are dissected from the ankylosed joint to which they have become amalgamated, and the whole mass—patella, quadriceps and soft parts—is turned upward, exposing completely the anterior and lateral surfaces of the junction of the tibia and femur.

At this juncture the gliding of the lower part of the quadriceps muscle and its tendon on the lower end of the femur is tested, as well as their length. If this tendon and muscle do not glide up and down satisfactorily and are not of sufficient length, plastic work should be done to lengthen the tendon as well as to bring about its satisfactory gliding on the lower end of the femur. This is a very important feature of the operation, because if the tendon is not long enough to allow postoperative flexion, or if the quadriceps tendon is not free, serious interference with postoperative physical therapy or mobilization of the joint will occur.

It has been my practice to remove all immobilizing splints at the end of two weeks and to institute active and passive motion. If the quadriceps tendon were severed, this early postoperative treatment would certainly jeopardize union. Again, the severance of the quadriceps muscle and tendon and the dissecting downward of the distal portion seriously involve the gliding structures above the patella, which may not have been damaged or destroyed by the original pathologic changes that produced the ankylosis.

After the patella, quadriceps and soft parts have been turned upward *en masse*, one is ready for the bone arthroplasty. With a broad osteotome parallel, broad V-shaped incisions with the apex downward are used in modeling the joint anteriorly and posteriorly.

The lower end of the femur as viewed from its anterior surface, is shaped into a wedge with an angulation of 120 degrees between its plane surfaces. This leaves the tibia with concave plane surfaces at an angle of 120 degrees to each other. These are in turn carefully modeled so as to receive with accurate fit the convex wedge-shaped surface of the femur. This is one of the original features of the operation and is an effective measure in the avoidance of lateral instability, in that, from a mechanical standpoint, weight-bearing forces the wedge contour of the lower end of the femur into the corresponding wedge shaped cavity of the upper end of the tibia. This peculiar contact practically insures stability, and consequently an unusual amount of laxity can be permitted by the removal of an ample amount of bone. A generous amount of bone, particularly at the posterior part of the joint, is removed from what was the tibia and femur, and the remainder is so shaped that it will imitate so far as possible the normal contour of the joint. Great care should be taken not to leave any blocks of bone attached to soft parts in the popliteal space because of the danger of their acting after operation as osteogenic material. It

must be remembered, of course, that the removal of too much bone will favor instability, but the wedge shaped method just described markedly diminishes this possibility.

Great care should be taken to leave the bony surfaces as smooth and plane as possible to facilitate gliding. This is usually best accomplished with a sharp, 1½ inch osteotome, but a file may be used, if necessary. A close study of the conformation of the bony surfaces of the new joint should be made in order to shape them most favorably for the function of joint motion. The proper conformation of the joint should then be tested by flexing the knee to beyond a right angle. Free motion without impingement at any point should be striven for, before the free fascia and fat graft are obtained. To insure this the patellar ligament with its dovetail bone fragment is replaced temporarily in the original mortise bed.

The joint is again flexed very cautiously to at least a right angle, to check up on the contours and to insure free excursion of the quadriceps tendon and muscle, so that postoperative physical therapy will not be prevented from securing the desired motion.

The joint is then packed with hot saline compresses, while a rectangular graft of fascia lata and fat is being obtained from the central portion of the outer aspect of the thigh. Being a semifluid substance, the fat under pressure after joint closure practically flows into the cavities and absolutely fills up all intra-articular dead spaces, thus preventing the formation of hematoma. For this reason the inclusion of fat with the fascia lata graft seems to me very valuable, and I can not agree with those who advocate the use of fascia lata alone.

If sufficient fat can be obtained with the fascia, the superior portion of the graft is split and the undivided portion placed between the tibia and the femur. The fascial portion of the split end is turned upward and inserted between the lower end of the femur and the quadriceps tendon, and the patella, while the fatty portion is turned downward and placed between the upper end of the tibia and ligamentum patellae and the patella. The graft is sutured with chromic catgut number 1 to the remains of the capsule and soft tissues. The remains of the capsule are then sutured medially and laterally with chromic catgut number 1, the skin is closed with plain catgut number 0, and sterile dressings are applied.

Moleskin straps are applied medially and laterally to the lower leg for traction, and a cast is applied, so constructed as to allow for traction by means of the moleskin. The tourniquet is not removed until the plaster, applied from below upward, has reached it. Removal of the tourniquet before closure of the wound is to be condemned in that in an arthroplasty there are such broad surfaces of raw bone that the large amount of bone ooze cannot be controlled by ligature. Careful observation shows that a larger amount of bleeding will come from the cut bone surface than from the small blood vessels, which will escape ligature if the tourniquet is left on. The compression and immobilizing effect of the well molded plaster of paris with all joint spaces filled with the fat and fascia graft acts as a marked hemostatic influence, and it is therefore preferable to leave the tourniquet on during closure of the wound and application of the cast, thus preventing the very considerable oozing from the bone surfaces which would occur were it

removed. The hazard of hematoma is a real one and should be carefully guarded against.

A pulley and traction apparatus on the bed must be ready for immediate application when the patient returns from the operating room. The patient is held completely under the anesthetic until traction of 15 pounds (68 Kg) is well established on the limb. This is done to prevent muscle spasm, which is likely to occur as the patient comes out from under the anesthetic and which might cause the approximation of the bone surfaces and the crushing of the fascia and fat graft between the bone surfaces. The latter might be a real calamity, leading to ankylosis.

This traction is continued for at least a month and a half after the plaster has been removed and the massage begun. Even after the patient goes home, the traction is maintained throughout the night, although during the day the patient is allowed to walk with crutches, without weight bearing, the latter not being permitted until at least two months after operation.

If, at the end of from three to six months, lateral mobility persists, Hey Groves recommends a second operation to reinforce lateral ligaments. This has not been found necessary with my technic, as in every case the joint has had most satisfactory lateral stability. But I have in several cases done secondary operations to sever restricting bands of fascia or scar tissue lateral to or above the patella which were limiting mobility, and the results have been excellent.

These operations have varied in degree from a short incision and the severance of a small band or two of fascia or connective tissue to an extensive operation in which even the new-formed joint has been entered and extensive soft parts have been severed.

I believe this is a rather radical step that has not been practiced by other men, and I feel very enthusiastic about secondary operations to overcome tissue contractures interfering with motion.

Pain does not usually persist after the first series of postoperative treatments.

The muscles gradually regain their ability to contract, even if they have been inactive for years, the reflexes reappear, the different types of sensation—superficial and deep, paresthesia and sensation of position—are at length reestablished, as in a normal knee.

The nearthroses possess still another characteristic once established, they are never the seat of effusion or of swelling. They seem to be resistant to all hematogenous arthritic processes.

The artificial joint created by the surgeon to relieve ankylosis is by no means an anatomically normal joint. It suffices that there is a joint which functions well (fig 7).

PROGNOSIS

With proper selection of cases, meticulous attention to technic and intelligent postoperative physical therapy, the prognosis for arthroplasty of the knee is good.

With regard to the advisability of operating on a bony ankylosis due to tuberculosis, there is the greatest difference of opinion. I believe that arthroplasty should be approached with due conservatism in such cases but not pessimism. If in the roentgenograms which should be taken in several planes, there are evidences of richly pocketed or cavity formation, or areas of extreme osteoporosis the case is unfavorable, but if the bone structure appears fairly uniform and there are no other unfavorable conditions arthroplasty should be successful. Some of my most brilliant results have been in cases of healed tuberculosis. It should

be emphasized, however, that all evidence of original tuberculous process must have been entirely eliminated for at least four years before this operation is attempted and the roentgenograms should show an unusual homogeneity as to structure of the bone throughout the joint area. At least one year should have elapsed since the last symptom if the infection was pyogenic in character. It is rarely wise to operate in cases of arthritis deformans.

Next to the hip, arthroplasty of the knee has made the greatest strides during the last decade, and such operations on both joints should be recognized as a trustworthy surgical procedure.

INDICATIONS FOR ARTHROPLASTY

Those who have had the widest experience and the greatest success with arthroplasty are unanimous in urging careful selection of patients. In so doing, the following points should be considered:

- 1 The original cause of the ankylosis
- 2 The position of ankylosis (flexion, extension, hyperextension)
- 3 The condition of the patient—not merely the general physical resistance but the condition of the soft parts overlying the joint. Extensive scar tissue, if it cannot be replaced with healthy tissue, is very unfavorable. Extensive adherence of the quadriceps tendon and muscle is also a handicap.
- 4 The psychic, social and occupational factors must all be weighed.

57 West Fifty-Seventh Street

KNEE JOINT ARTHROPLASTY

W. RUSSELL MACAUSLAND, M.D.

BOSTON

In previous publications I have summarized and discussed the general aspects of ankylosis and arthroplasty of the knee joint. In this report, therefore, I shall present a few features of knee arthroplasty that have stood out prominently in our experience with the procedure at the MacAusland Clinic and show how a number of cases in which we have performed arthroplasties of the knee have withstood the test of time, as to both function and stability.

In our experience with knee arthroplasty, the complication of infection of the operative wound, from latent foci of infection has been not infrequently encountered. This factor does not seem to have been stressed by other surgeons, and possibly they have not encountered it to the same extent. That the complication is not due to operative sepsis I am certain, because the infection has appeared too late after intervention. In the four cases of which I am giving detailed descriptions it may be noted that the infection could definitely be traced to a dormant focus situated elsewhere in the body.

CASE 1—A man aged 50, a rancher, had a complete ankylosis of the knee as the result of a streptococcal infection from his tonsils eight years before we treated him. In spite of his age all factors were conducive to success and we considered the prognosis excellent. On the fourth day after the arthroplasty the patient was somewhat uncomfortable from abdominal distention and gas and for the next two weeks this distention continued to come and go. On the eleventh day after the

arthroplasty, considerable pus was found under the skin flap covering the knee, but there was no definite indication of pus within the joint. By the eighteenth day the patient had a tense, swollen abdomen and was practically moribund, in spite of the efforts of four surgeons who had been consulted regarding the symptoms. Pus was found in the joint region itself. A laparotomy was performed and a gastric perforation found. The surgical and medical aspects of the case then progressed favorably. It is now eight years since the arthroplasty and the patient has flexion of the knee to a right angle and is able to extend his leg completely. The joint is stable and painless. The patient rides with comfort and he is able to play eighteen holes of golf regularly without experiencing any ill effect.

CASE 2—A man aged 26, a state trooper had a completely ankylosed knee as the result of "rheumatic fever." His general health was excellent. Ten days after an arthroplasty was done abscess of the jaw developed and the knee wound became septic. The outcome in this case was poor. It has now been two years since the arthroplasty was done. The knee is again ankylosed, although the patella is slightly movable. Operation will probably be considered again in this case although the knee is ankylosed at about a 12 degree angle and is therefore in excellent position for walking.

CASE 3—A woman in the late twenties had had a multiple infectious arthritis. Arthroplasty of the knee was not performed until a year and a half after the acute process had quieted down. Six weeks after the arthroplasty, a subacute gonorrheal infection in the pelvis became active, and the motion, which up to that time had been free and painless up to 30 degrees, gradually shut down. There was no drainage at any time. The patient now has a stiff knee, and several other joints are ankylosed as the result of this acute infectious process.

CASE 4—A man aged 28 had a completely ankylosed knee as the result of sepsis following the use of tongs in the treatment of a fracture of the lower third of the femur. The arthroplasty of the knee was not performed until nearly two years had elapsed from the healing of the sinuses. When we opened the joint, we found some rust embedded in the old scar tissue around the tong holes, but it seemed to be so high above the joint and so much time had elapsed since the active infection, that we anticipated no trouble. On the tenth day after the arthroplasty, however, there was a slight discharge from the original pin holes, and drainage continued from the posterior aspect of the knee off and on for a period of three months. The chances of gaining motion were thereby seriously interfered with. It is now over a year since the arthroplasty, and the patient is beginning to have a little free motion in the joint.

From our experience I conclude that a thorough examination of the patient before arthroplasty, for the purpose of determining any focus of latent infection, is of vital importance. I do not mean to imply that we have not checked the general condition of all our patients, but without doubt the examination has not been sufficiently thorough. Every possible site of a latent infection—pelvis tonsils and teeth—must be carefully checked. I believe that if these precautionary measures are taken the number of cases of infection will be decreased.

Again I want to emphasize the well known maxim that an arthroplasty must not be performed until one is certain that the original acute process has quieted down. In our clinic we do not advise arthroplasty until one and one-half years after all signs of infection have disappeared. When the joint is ankylosed as the result of a tuberculous process, mobilization is approached with extreme caution, for such diseased joints may retain small walled-off foci throughout life. In the very rare case in which the health is excellent and in which there has been no evidence of an active process for years, a tuberculous joint may be mobilized successfully. On the whole, we consider that arthroplasty is not advisable in these cases.

The age of the patient is another factor that must be given careful consideration. The most favorable ages for arthroplasty are those from adolescence to 40 or 45 years, but a mobilizing operation is not definitely contraindicated later in life, provided the bone and musculature are in healthy condition. Such was the case in the two patients, aged 50 years, whose histories are given in detail elsewhere in the paper.

A second feature of knee arthroplasty that in my opinion should be stressed is careful modeling of the joint surfaces. This provision of the technic is emphasized for two reasons: first, to preserve the stability of the joint, and second, to avoid the development of arthritic changes in later years. We never sacrifice stability for the sake of obtaining motion. It is better to allow the joint to remain stiff than to create a hypermobile joint, for an unstable knee, even when efficiently protected by a brace, is a handicap and subject to strain and the consequent development of arthritic changes. The preservation of stability presented a difficult problem in the early days of arthroplasty, but now, owing to the refinement of technic, one does not hear so much about lateral instability.

There is a provision made in our technic to preserve stability and to ensure a joint that will not be subject to arthritic changes.

OPERATIVE TECHNIC

A longitudinal skin incision is made, extending downward over the center of the patella. The fascia, quadriceps tendon and capsule are incised by means of either a goblet-shaped incision or a linear incision. The goblet-shaped incision provides for lengthening the quadriceps tendon when the knee has been stiff in extension for a long period. The patella is chiseled from the femur, exposing the tibiofemoral joint. The ligamentous structures are freed from their attachment to the tibia and the femur. Attention is now given to freeing the joint line and modeling the articular surfaces. The tibia is first separated from the femur by means of a gouge, the diameter of which corresponds to that of the femoral condyle in the adult. The articular surface is cut in such a fashion that two semicircular convexities are formed. As the operation proceeds, an assistant flexes the knee so that the remaining lamellae uniting the epiphysis of the posterior region are divided. About 1 cm. of bone is then removed from the femoral surfaces.

The tibial and femoral surfaces are now remodeled to conform as closely as possible to the normal contour of the joint. A well defined spine, corresponding to the intercondylar notch, is left between the concavities in the tibia to ensure stability.

The articular surfaces are next fitted to make sure that sufficient bone has been removed. The surfaces must glide smoothly without any irregular hitches occurring during flexion and extension.

A space into which the patella will fit is cupped out of the upper surface of the femur. As a rule, the patella will be found to be hypertrophied, and it is necessary to narrow it by first removing a third from each side longitudinally and then taking about one third from the joint surface of the remaining section.

The bone surfaces are smoothed by means of files and rasps. This filing, in addition to smoothing the edges, drives a bone dust into the open spaces, which aids in controlling hemostasis and, by roughening the surfaces of the resected edge, causes the aponeurosis of the fascial transplant to adhere more firmly.

The next step is to remove from the opposite leg a large piece of fascia lata, of sufficient size to cover both condyles, both tibial cavities, and the under surface of the patella. The operator first sutures the long flap of fascia over the tibial cavities, at their anterior surface. He then allows the flap to drop back into the popliteal space to a point about $2\frac{1}{2}$ inches upon the posterior surface of the femur. The flap is then fixed to the lateral surface of the tibia with interrupted sutures. Next, the fascia is swept around the femur and wrapped over its anterior surface for about $2\frac{1}{2}$ inches and tied tightly in place with a purse-string suture. The remaining part of the flap is then turned down and sutured to the top surface of the tibia.

The deflected flap, consisting of the patella, capsule, quadriceps and fascia, is replaced. The elongated quadriceps and capsule are sutured, and the skin is closed. A plaster bandage or intrinsic traction splint is applied with the knee in 35 to 40 degrees flexion. The leg is placed in an elevated position in bed.

The after-care must be carefully supervised. About two weeks after the operation, the plaster bandage is split and the leg placed in a ring caliper traction in 35 degrees flexion. This caliper is so arranged that knee motion is possible. By means of an overhead pulley, the patient begins passive motions while in bed, carrying them out usually two or three times a day. The movement should be gentle at first and then gradually increased. Active movements are attempted about the third or fifth week. Massage of the thigh and calf is begun in five or six weeks. About the sixth week the patient can usually walk with crutches. No actual weight bearing is allowed until the lateral ligaments have tightened.

The series of knee joint arthroplasties at our clinic has not been a large one, possibly because we have been extremely cautious in our selection of cases. Unfortunately, I am not able to give an analysis of our complete series, as we were not able to locate many of the patients, despite our painstaking efforts. From our group of cases I have selected five, in addition to the cases described at the beginning of the paper, on which we performed arthroplasties of the knee from six to twenty-three years ago. Our study shows that these patients secured stable and functional knees and that they have continued in this same status for over a period of years, without developing any arthritic changes.

CASE 5—T S, a man aged 21, had a completely ankylosed knee as the result of a chronic infectious arthritis, which was superimposed on an injury to the joint when he was 8 years of age. Six months after the injury the knee was ankylosed in flexion, and we made two unsuccessful attempts to mobilize it by manipulation. It was twelve years before we saw the patient again, and meantime an arthritis had developed in the joint. The knee was ankylosed in 90 degrees flexion.

March 24, 1927, an arthroplasty of the knee was done. The case progressed favorably and the motion increased daily.

Feb. 2, 1933, nearly six years after the arthroplasty, the knee had function of 85 degrees and was a good weight-bearing joint. The only complaint of the patient was that the leg was fatigued after he had been standing on his feet all day at work.

CASE 6—C B, a miner aged 50 had a fibrous ankylosis of the right knee which had resulted from an injury to the lower part of the thigh four years previously. During the year following the injury the joint had been aspirated and drained several times. When we first saw the patient the sinuses had been healed for over a year and the knee had been partially ankylosed for three years. The knee allowed 15 degrees flexion when the patient put his foot on the floor and pushed against

the knee, but there was no voluntary motion. The patient's general health was excellent.

April 29, 1924, an arthroplasty was performed. The case progressed favorably.

In April, 1931, seven years after the arthroplasty, the patient had motion to nearly a right angle and a good stable knee. Shortly after this report was made, the patient disappeared, and his family believe that he committed suicide.

CASE 7—R H, a woman aged 24 had an ankylosed patella following a comminuted condylar fracture of the lower femur.

Nov. 20, 1924, a subpatellar arthroplasty was performed. March 14, 1925, the patella was movable in all directions and the knee was stable. The patient was able to extend the leg voluntarily to within 15 degrees of full extension, but here the patella seemed to stop. A manipulation was done to break up the adhesions.

June 2, 1933, nine years after the arthroplasty, the patient had a stable and perfectly functional knee. Extension to 180 degrees and flexion to 90 degrees were possible.

CASE 8—E P, a woman, aged 30, in 1921 suffered an acute infection of the right knee, probably metastatic in origin from the tonsils. When we saw her in 1925, the knee was ankylosed in a few degrees hyperextension, with a slight knock-knee deformity. The patella was freely movable.

March 5 an arthroplasty was performed.

Feb. 13, 1933, the knee allowed function to 90 degrees and was practically, if not completely, stable. The patient told us that she had indulged in all activities for several years.

CASE 9—F O K, a male, early in 1909, suffered an acute gonorrheal infection in the left knee. The joint was opened and treated. Following the attack the knee was in good position, but there was no motion between the tibia and the femur or between the patella and the femur. Manipulations were unsuccessful in restoring motion.

Dec. 14, 1910, an arthroplasty was performed.

In February, 1933, twenty-three years later, the patient had a stable and functional knee. Sometimes he has to think which is the knee that was operated on.

From our study of the status of restored knee joints after a period of years, in my own cases and in those of other operators, I am convinced that arthroplasty is to be considered a standardized form of treatment for ankylosed knee joints. By this measure a knee that is both functional and capable of enduring can be obtained. The use of this procedure in the knee joint, however, still presents an exacting problem, and its success depends on a most careful selection of cases as well as precise technique. It is my opinion that if arthroplasty is to continue to hold its place in reconstructive surgery of the knee joint, and to increase its scope, careful consideration must be given to the outstanding factors and complications observed in each operator's experience. From my own experience I am convinced that arthroplasty of the knee joint must be approached with particular regard to the following factors: (1) the selection of the case with reference to the age of the patient, and the lapse of time from the flare-up of an acute process, (2) the preparation of the patient with reference to the presence of foci of latent infection, and (3) the use of an operative technique that assures the restoration of a joint that is not only functional but also stable.

412 Beacon Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. ALDFE AND MACALAND

DR. W. BARNETT OWEN, Louisville, Ky. In 1904 Dr. Murphy published his article on arthroplasty. Shortly after it was my good fortune to observe four arthroplasties of the knee for ankylosis from tuberculosis. In each instance there was an absolute failure. Of course the technique of arthroplasty has been greatly improved by this time, but I am still of the same opinion that a joint ankylosed from tuberculosis should not

Dr. Robert Helling Library

U. S. Medical College

32632

be subjected to arthroplasty. The indication for arthroplasty is principally in trauma, fracture, injury to the joint, ankylosis, and some pyogenic infections that have subsided. When that time is I am not prepared to say. I have operated in some of those cases and I thought that sufficient time had elapsed, only to find later that I was mistaken. I don't believe that one can tell when any joint is and will remain absolutely free of infection if operative intervention is instituted. Generally, I would say that more than 50 per cent of the limited number of cases I have had of arthroplasty of the knee joint have been satisfactory to me or to the patient. Arthritis has developed in a limited number. As is well known, arthroplasties of the jaw and of the elbow are much more favorably regarded because of the location of the joints. It is necessary to have stability in any joint, but that is not so imperative in a joint that is not weight bearing. One can have a very useful elbow that isn't absolutely stable, but it will have a good, painless range of normal and very helpful motion that is satisfactory to the patient. Dr. Albee has instituted new procedures that are unique and in his hands, I am sure, of great advantage.

DR J. S. SPEED, Memphis, Tenn. I am still of the opinion that there are economic reasons why one should refuse to do arthroplasties. I believe that the postoperative care and physical therapy are extremely important and that, unless the patient can afford to have these arthroplasties should not be recommended to them. Patients who do hard manual labor should be chosen with considerable thought, for the reason that many of them will not obtain a knee sufficiently strong and durable to stand the stress of their occupation. One should also make sure that the muscular development of the extremities is brought up to the highest possible point before the operation is undertaken. I believe that tuberculosis is a definite contraindication. It is true that Dr. Albee and many others have obtained excellent results in tuberculous joints, but there have been many disasters following it. The serious results that follow the lighting up of an old tuberculous process in a joint far outweigh the occasional good results that may be obtained. Another definite contraindication to arthroplasty is the joint that has become ankylosed following osteomyelitis. The infection here has involved the bony structure about the joint, and deep seated foci of infection may remain active in such bones for an indefinite period of time. Any operation on such a bone is likely to be followed by a lighting up of the old infection. I have attempted arthroplasties on the knee in six cases with stiffness and deformity following osteomyelitis. In all these cases the infection was relighted and the arthroplasty a complete failure. I have come to the definite conclusion that arthroplasty should not be advised in joints ankylosed from osteomyelitis. I have seen an aseptic sequestration of portions of the newly formed condyles of the tibia or femur following arthroplasty of the knee with resulting irregularity of the weight-bearing surface of the joint and some instability. The cause for this aseptic necrosis is probably a disturbance in the blood supply of the bone at the time of operation. It is an interesting observation that the roentgenographic appearance of the joint following arthroplasty is not a true indication as regards its function. Many joints showing irregularities in the articular surfaces and the formation of osteophytes or exostoses about the joint have proved to be good functional joints. On the other hand, some that have shown remarkably good contours from a roentgenologic standpoint have either been painful or have not secured a satisfactory range of motion. I prefer not to gain motion too rapidly following the operation but to carry it along gradually, forcing an increase in motion as muscle development improves sufficiently to take care of it. I think that in this way many cases of instability in joints following arthroplasties may be avoided.

DR EDWIN W. RIERSON, Chicago. The subject of arthroplasty is of such great importance that I think an attempt should be made to arrive at some unanimity of thought. I observed that Dr. MacAusland favors the Putti incision. I tried this incision in a long series of cases but had so much trouble with the lack of blood supply in the ends of the flap directed upward that I abandoned it, and I do not propose to use it any more. A straight incision down the front of the knee to the inner side of the patella, as mentioned by Dr. Speed, is satisfactory for any arthroplasty of the knee. I do not

think that it is always necessary to detach the tubercle of the tibia, as shown by Dr. Albee, but it is very satisfactory and I have used this method a number of times in the last few years and find that it works extremely well. The bone of the tubercle of the tibia unites much more rapidly and more satisfactorily than does the quadriceps tendon when it is cut above the patella. The stability of the knee joint is a point that has been insisted on, in my opinion, too much, in certain classes of cases. Take a young woman who is employed at light work and who doesn't have to follow the plow. It is much to her advantage to have a knee that she can bend enough to get out of the way of other people in the street car or automobile or while sitting in the ordinary chair. I have questioned a number of young women on whom I have performed an arthroplasty of the knee, and although they had some lateral instability of the knee joint they were unanimous in stating that they much prefer to have a moderately unstable knee which they can get out of the way of other people's feet. Next about the ingenious method of Dr. Albee in cutting a V-shaped notch into the lower end of the femur. It seems to me that it is not good mechanically and I think that it would not be good practically. Most of his other ideas I agree with thoroughly. It doesn't seem reasonable to cut off the two most important weight bearing parts of the lower end of the femur and to substitute for them the intercondylar notch as the weight-bearing part of the knee joint. I don't think it is necessary, because I have so many good knee arthroplasties in cases in which the lower end of the femur was cut straight across in the proper way. I think that no tuberculous joint should ever have an arthroplasty performed on it. I have done two arthroplasties in a presumably healed tuberculous joint and the tuberculosis recurred in both. Next in regard to the type of infection causing the ankylosis. I think the gonorrheal ankylosis is by all odds the best to attack in an operative way. Next are those cases of infectious acute arthritis which used to be called acute rheumatism, in which ankylosis occurs rapidly. I will once more refer as I have many times before, to the question of fat necrosis in arthroplasties of the knee. I have had seven cases of women who were very fat and on whom I did excellent knee arthroplasties. A fat necrosis occurred, at first apparently without any infection, and each one of those knees became reankylosed and the operation consequently failed.

DR FRED H. ALBEE, New York. This discussion has been most interesting. There was, however, a misunderstanding concerning the wedge modeling. The purpose is not to allow the crest of this wedge to bear any more weight than any portion of the new joint surface. It is a convex wedge the surface resting in a concave joint surface. When the limb is lifted from the floor the joint surfaces drop away from each other, allowing free motion. Weight bearing jams the wedge surface into a concave wedge cavity, thus giving lateral stability.

DR W. R. MACAUSLAND, Boston. I think that some of the men do not understand why the quadriceps is elongated. I have no argument with anybody about an incision. The first question is: Does the joint check up as a functional and stable joint afterward? I prefer the Bennett elongation of the quadriceps for this reason. If one places a knee joint after arthroplasty in extension, one will have a lot of trouble gaining motion. I train the knees before arthroplasty and increase the muscular tone of the thigh by violent contraction of the quadriceps preparatory to operation. If a knee after arthroplasty is put in about 30 to 35 degrees flexion, even though the quadriceps has been cut (about which operation I have had not one bit of difficulty), earlier motion can be started. I begin at 35 degrees flexion and move to straight extension by the apparatus devised by Dr. Warren White for me. I start rather early motion by voluntary muscle contraction. That is the object of the Bennett elongation of the quadriceps as applied to arthroplasty of the knee.

Advances in Cardiology—In this century there have been two notable advances in cardiology: first, the recognition of auricular fibrillation and second the perception of coronary infarction as the pathological basis of one type of anginal pain—the "status anginosus"—Hay, John. *Certain Aspects of Coronary Thrombosis*. *Lancet* 2:787 (Oct 7) 1933.

PRECONCEPTIONAL AND PRENATAL INFLUENCES AFFECTING THE NEW-BORN

LEE BIVINGS, M.D.
ATLANTA, GA

In attempting to determine the causes of umbilical hernia in the Negro it was noticed that there was a definite relationship between variations in the incidence of hernia, birth rate, average birth weight, prematurity and deaths during the first week of life. Seasonal variations occurring consistently in each study strongly suggest the importance of the preconceptional and early prenatal periods and give some indications as to possible causes.

Since syphilis might influence some of these conditions, all cases in which either the mother or the infant showed a positive Wassermann reaction were excluded.

BIRTH RATE

There were 5,564 live Negro births in Atlanta during 1930, 1931 and 1932. There was an average of 491 infants born during the winter quarter, 458 in spring, 454 in summer, and 440 in the fall. The low rate of 440 in the fall corresponds to the group conceived during the winter quarter and the high rate of 491 to the group conceived in the spring.

AVERAGE BIRTH WEIGHTS

The average birth weight of two groups of white infants was determined to compare with that of the Negro. The private patient group of 955 white infants averaged 7 pounds 10 ounces (3,460 Gm). The ward group of 1,801 white infants averaged 7 pounds 9 ounces (3,430 Gm), and the group of normal Negro infants averaged 6 pounds 14 ounces (3,120 Gm).

There is little difference in the white groups but nearly 12 ounces (340 Gm) difference between the combined white groups and the Negro group.

Chart 1 shows the trend to seasonal variations in the two groups of 1,154 and 1,272 Negro infants. There seems to be a tendency to follow the curve of the average hours of sunshine for Atlanta for the same time interval. This tendency holds true for white infants. A more detailed study of birth weights will be published at a later date.

There is also a geographic variation in birth weights. In a study of approximately 1,000 white infants over a period of a year, E. D. Plass¹ reports for Iowa City an average of 7 pounds 5 ounces (3,320 Gm). Martha Eliot² reports an average birth weight of 7 pounds 6 ounces (3,350 Gm) from New Haven, Conn.

C. C. Rudolph³ reports an average of 7 pounds 7 ounces (3,375 Gm) from St. Petersburg, Fla., and the Atlanta average for white infants is 7 pounds 9 ounces (3,430 Gm).

It would seem that there is a tendency for the average birth weight to increase in the southern portion of the United States.

UMBILICAL HERNIA

During the embryologic stage in development the umbilical ring is the remains of the coelomic funnel as it passes through the linea alba.

The xeroform for this study was furnished through the courtesy of Merd John on & Co.
From the Departments of Pediatrics and Obstetrics, Emory University School of Medicine.
Head before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.
1. Personal communication to the author.

Between the second and the third month of fetal life the intestine recedes into the abdominal cavity and leaves a depression in the wall which lies above and to the right of the umbilical arteries and below and to the left of the umbilical vein. Cullen² termed this the weak spot, and it is said to be the weakest place in the abdominal wall. It is the relaxation of this umbilical ring that allows the protrusion of the intestine and peritoneum, which make up the umbilical hernia contents. The umbilical fascia is present as a reinforcement in comparatively few cases.

Since these hernias appear during the first few days of life, the factors causing relaxation of the ring are unquestionably prenatal in time. Therefore it would seem probable that the presence of an umbilical hernia, in an otherwise normal infant, is caused by an inherent weakness in the connective tissue framework of the body. There is a simple relaxation of the ring and a stretching of scar tissue which could normally withstand the increased intra-abdominal pressure caused by crying and straining. It is probable that the weakness dates back to the early weeks of pregnancy or even to some deficiency during the preconceptional period. This is supported by the seasonal variations shown later.

Chart 1—Trend to seasonal variations in two groups of Negro births

The incidence of umbilical hernia in 2,023 normal Negro infants was 270 per thousand. In 1,808 white infants the incidence was 82 per thousand.

In a study of the incidence according to the months of birth, the winter quarter showed an average of 260 per thousand, spring, 270, summer, 270, and fall, 386 per thousand. The group showing the highest incidence, in the fall, was conceived in the winter quarter.

PREMATURITY

In the Emory University Division of Grady Hospital all Negro infants weighing 5 pounds 8 ounces (2,495 Gm) or less are classed as premature infants. Stillbirths and syphilitic infants were excluded.

Prematurity was approximately twice as common in 3,255 Negro infants as in 1,801 white infants.

In a study of the seasonal variations in the rate of prematurity in the Negroes, it was found that there were 86 per thousand in the winter quarter, 108 in the spring, 86 in the summer, and 133 per thousand in the fall. The high rate corresponds to the group conceived in the winter quarter.

2. Cullen, T. S. Embryology, Anatomy and Diseases of the Umbilicus. Philadelphia: W. B. Saunders Company, 1916, p. 23.

There seems to be a possible relationship between the annual rate of prematurity in the Negro and the total hours of sunshine for the year, as shown in table 1

The highest rate occurred in 1932, when the hours of sunshine were lowest. However, it is probable that other factors play a part in determining the rate

DEATHS DURING THE FIRST WEEK OF LIFE

The following significant statement is taken from the report of the New York Health Commission³ for the year 1932: "In the first six days after birth, one

TABLE 1—Possible Relationship Between Rate of Prematurity and Hours of Sunshine

Year	Total Hours of Sunshine (Atlanta)	Rate of Prematurity per 1,000 Live Births
1930	2,870	109
1931	3,064	88
1932	2,660	113

half of all infant deaths occur, and the greater proportion are due to prenatal and natal causes. Moreover, little change has occurred in fifteen years, the 40 per cent reduction in infant mortality between 1915 and 1930 has been due chiefly to the saving of life among older infants."

Table 2 shows that the same is true of 5,564 Negro infants born in Atlanta during 1930, 1931 and 1932

The seasonal variations in the rate of death during the first week of life for this group is as follows: winter quarter, 46 per thousand, spring, 41 per thousand, summer, 43 per thousand, fall, 58 per thousand. The group showing the highest rate (fall) was conceived in the winter quarter.

EXPERIMENTAL STUDY

An attempt was made to determine what effect, if any, viosterol might have on the infants of Negro mothers to whom it was given in the late weeks of pregnancy. One hundred and twenty-five mothers, with negative Wassermann reactions, were given 20 drops daily for an average period of six weeks before delivery. The average birth weight of ninety-three of these infants was 7 pounds 2 ounces (3,240 Gm.), as

TABLE 2—Negro Infant Mortality

Year	Deaths During the First Year per 1,000 Live Births	Deaths During the First Week per 1,000 Live Births
1930	145	60
1931	118	62
1932	90	43

compared with an average of 6 pounds 14 ounces (3,125 Gm.) for 290 controls born during the same period.

The incidence of umbilical hernia for the experimental group of ninety-three was 300 per thousand, as compared with an incidence of 270 per thousand for the average Negro infant.

The group is too small to be especially significant, however, it would seem to indicate that the birth weight was influenced favorably in late pregnancy, while the incidence of umbilical hernia was not affected. As previously brought out it would seem that umbilical hernia is influenced early in pregnancy.

SUMMARY

Chart 2 shows a summary of the seasonal variation of the incidence of umbilical hernia, the incidence of prematurity, the birth rate and deaths during the first week of life. There is a sharp rise in the fall quarter for hernia, prematurity and deaths during the first week of life, and a decline in the birth rate.

A reasonable explanation is offered in following the arrows from the groups showing these changes to their period of conception, which occurs in midwinter. It is interesting to speculate as to what factors might cause these weaknesses in infants conceived in the midwinter months.

It has been brought out in this study that umbilical hernia, prematurity and deaths during the first week of life are much more common in the Negro than in the white infant.

The curve of birth weight shows a tendency to follow the curve of sunshine.

Negro infants conceived in the winter quarter show a decided increase in the weaknesses mentioned.

Since the pigmented skin of the Negro is known to filter out much of the available ultraviolet radiation it seems not unreasonable to suspect that deficiencies in

Chart 2—Summary. A, average birth rate of 5,564 infants; B, average incidence of hernia in 2,623; C, average incidence of prematurity in 3,255; D, death rate in first week of life among 5,564 infants. The arrows point to the months of conception.

vitamin D may play an important part in causing these defects and may partially explain the increased frequency in the Negro, especially when pregnancy begins in midwinter.

Maurer and Tsai⁴ think that vitamin B complex deficiencies have an important influence on the pregnant mother. It is during the winter quarter that the average diet is most deficient in vitamin B complex.

CONCLUSION

It seems probable that the periods of greatest importance for the well being of the new-born infant are those months immediately preceding pregnancy and the early months of pregnancy.

205 Exchange Building

ABSTRACT OF DISCUSSION

DR. FRED L. ADAIR, Chicago: Dr. Bivings has touched on vital influences which affect not only individuals but also social groups. The effect of these influences on the development of umbilical hernia would be of greater importance as the manifestation of a general law than as a condition in itself. In considering preconceptional influences, one has to consider

³ Report of the New York Health Commission for 1932.

⁴ Maurer, Siegfried and Tsai, L. S. Illinois M. J. 61: 30 (Jan) 1932.

the hereditary influences that are carried in the genes of the various chromosomes of both germ cells and factors that influence the germ cells in whole or in part and are transmitted to the embryo and affect it in its individual development, the former being hereditary, as an integral part of germ plasma, and the latter being nonhereditary. Antenatal influences begin after fertilization takes place and are environmental but nevertheless modify more or less the hereditary and transmissible factors mentioned. So far as influences operating on the actual development are concerned they must begin during the early weeks of gestation. Once tissue development and organogenesis are under way at two months' gestation, the remaining portion of intra-uterine life is largely one of growth. The pathology of this early gestational period is largely teratologic, while later intra-uterine life is subject to diseases affecting physiologic and anatomic growth. Umbilical hernia is a developmental tissue growth defect at the umbilical ring. This may be hereditary, as is indicated by the observation that this condition is more frequent in the Negro race. If it is due to any prenatal influences that affect embryonic and fetal development, they must operate in the early weeks of gestation before organ and tissue development are well under way. Factors affecting growth and extrinsic diseases may, of course, be potent during any period of gestation. Such conditions as congenital heart defect or spina bifida would have their roots in the preconceptional period or early embryonic life. Syphilis and other congenital infectious diseases might affect the growing progeny at any time. To be considered during these periods are (1) hereditary conditions and (2) nonhereditary transmissible disorders, (a) early manifestations of preconceptional factors and environmental influences on the embryo which cause either death or maldevelopment, and (b) late manifestations of maldevelopments due to the factors mentioned, disturbed growth, and the results of congenital disease derived from the mother, usually infections or toxic manifestations. These various disorders may cause embryonic or fetal death or neonatal death or may manifest themselves variously during infancy, childhood, adolescence, maturity or retrogression. These disorders are not solely physical and anatomic but are also physiologic and affect the structures of the central nervous system as well as the organs of digestion.

DR RAYMOND L. SCHULZ, Los Angeles. Dr Bivings is correct in stating that preconceptional conditions are the cause of these deformities. I am absolutely convinced of the correctness of the theory expressed by R. Clay Jackson. I will give some idea of how this system works. A predominance in the sex of the offspring has been accomplished in controlled experimental animals. For example of a pair of rabbits, the male is kept in complete shade while the doe is kept out in the sunshine for a month or longer. During twilight and the night, proximity is permitted to insure mating at the expected time. The resultant litter will approximate 80 per cent males. By reversing the environmental conditions a similar female predominance is secured. The sex of the offspring favors the sheltered parent protected from sunlight. Besides the sunshine-shelter differential in man other factors come into play, namely, the relative weights of the parents and the colors of the hair and eyes. How are abnormalities produced? In bisexual conjugation if there is a good contrast in the cellular potentials of the gametes, the stronger will impose its sex on the offspring. If the two gametic potentials are about equal there will be a contest of two forces within the new organism each trying to impose its characteristics on the offspring. These conflicts may result in constitutional disturbances, anatomic, endocrine, neurologic and immunologic subnormalities. This is the threshold of a new era studying the pathologic results caused by incorrect human breeding. When parents will adjust their sunshine and shelter habits in accord with their natural gradients they can be assured of obtaining 100 per cent perfect male or female products.

DR LEE BIVINGS, Atlanta, Ga. Dr Adair mentioned the possible connection between defects I discussed and other defects. The great prevalence of rickets in the Negro is well known. It was not possible in my study of Negro infants to be able to examine each one but I did so in the study of 1608 white infants. I was unable to connect the incidence of umbilical hernia with

rickets or any developmental defect. Many of the finest looking babies seen had umbilical hernias without any other sign of defect, without any evidence of rickets, or without any evidence of inguinal hernia. I think the cause of umbilical hernia and many other defects is probably active early in pregnancy or even before pregnancy occurs. Dr Schulz commented on the effect of ultraviolet rays. The pigmented skin of the Negro filters out most of the ultraviolet radiation that he would ordinarily receive on the earth's surface. I attempted to correlate the effect of smoke and clouds and various conditions of that sort. There has been so little experimental work or actual tabulation of data on the subject of the effect of clouds and smoke on the ultraviolet rays that nothing exists on which to base a study. There has been some work done by the Mellon Institute in Pittsburgh in which it is shown that the seasonal variation in ultraviolet radiation is the same as sunshine, except that it is probably from 25 to 40 per cent of the total hours of sunshine quantitatively. Hess has shown experimentally that ultraviolet radiation as applied to rats is intercepted by the pigmentation. He took a group of white rats and a group of black rats and produced rickets by diet and then cured the rickets in the white rats but could not in the black rats because of their pigmented skin. The same thing naturally applies to the Negro. Rickets is very common, and the incidence of umbilical hernia and prematurity is much more common in the Negro than in the white race. I believe that the nutritional condition of the mother is the largest factor. Just what brings about the nutritional condition I cannot say, except that economic conditions do play a part. Dr McCord knows that many of these mothers coming to the hospital for delivery are actually hungry. That is bound to have an effect on their offspring, particularly if the condition has existed throughout the entire period of pregnancy. Just why the seasonal rise in there cannot be explained on nutritional grounds alone.

RADIOTHERAPY AS A METHOD OF IDENTIFYING CERTAIN VARIETIES OF TUMOR

ARTHUR U. DESJARDINS, M.D.
ROCHESTER, MINN.

Among the methods of identifying and classifying tumors, microscopic examination has for a long time stood preeminent. Until now, in fact, it has been the only method by which substantial accuracy in the identification of neoplasms can be achieved. Without microscopic examination the classification of new growths would be as rudimentary as it was before the development of microscopic pathology. From the standpoint of science in general and medicine in particular, the microscope undoubtedly is one of the most valuable instruments ever invented. If microscopic examination of diseased tissue does not invariably lead to accurate identification of lesions benign or malignant, the fault does not lie with the instrument but with the human observer, the accuracy of whose observations and deductions depends on the quality of the optical system of the microscope, the acuity of his own vision, the range and depth of his knowledge of pathology and other phases of medicine, his experience and, finally, his general intelligence. A number of factors may make the task of the pathologist more or less difficult. The tissue that he receives may or may not have been an essential part of the tumor, the excised tissue may have come from a part of the growth that may not truly represent the neoplasm as a whole. The interval between removal of the specimen and examination may have been so long as to have allowed the tissue to

From the Section on Therapeutic Radiology, The Mayo Clinic.
Read before the Section on Radiology at the Eighty-fourth Annual
Session of the American Medical Association, Milwaukee, June 16, 1933.

degenerate. The specimen may have been improperly fixed, or the fixative may have undergone deterioration. The tumor may present unusual features or may be of a kind with which the pathologist may not have had extended experience. Under the circumstances, absolute accuracy in the identification of lesions is, from a practical standpoint, an unattainable ideal. As evidence it is only necessary to mention the common inability of pathologists of great experience to agree on the character of a given tumor. Moreover pathology, like all other branches of knowledge still has dark corners into which light has not yet penetrated. In spite of these difficulties, however, the ability of an experienced pathologist to identify tumors accurately in a large proportion of cases is quite remarkable.

Great as is the ability of the really competent pathologist to recognize the true character of cellular changes, the condition of tissues and the steps through which such alterations have been brought about, cases are occasionally encountered in which his interpretation proves to have been erroneous. Sometimes he alters his opinion spontaneously, or he may be forced to do so by subsequent developments which invalidate his original view. In other words, the pathologist as a human being is subject to error, and too commonly the clinician and surgeon expect too much from the pathologist, who cannot relieve the impossible. Moreover, the average physician has come to rely too blindly on the verdicts of the pathologist, and conflicting physical, clinical and roentgenologic data are sometimes disregarded when their analysis would lead to a more accurate diagnosis than unquestioning reliance on microscopic observations, which, for various reasons, may not be trustworthy. The excessive faith of many physicians has probably arisen from the close collaboration that has grown up between the surgeon and the pathologist. Exceedingly valuable as such collaboration undoubtedly is, because microscopic inspection of diseased tissues serves either to confirm or to correct the necessarily rough visual impressions of the surgeon, whose judgment would otherwise have to depend on unreliable surface appearances, microscopic examination of a tumor may not necessarily be conclusive. In spite of the accumulated knowledge and experience in this field of medicine, the identification, and especially the classification, of tumors are still surrounded by a certain measure of uncertainty. The most experienced pathologists frankly admit that they are often puzzled and uncertain. Indeed, the greater the knowledge and experience of the pathologist, the more ready he is to admit doubt or confess to actual ignorance.

My object is not to belittle the pathologist but to draw attention to the fact that, in some cases, another method of identifying and classifying certain varieties of neoplasms is available. The range of usefulness of this method is not nearly so broad as that of the pathologic method, but within its own range it is as dependable as, and sometimes actually more dependable than, the microscope. I refer to radiotherapy or, more specifically, to the reaction of certain kinds of tumor to roentgen rays or radium. Like the pathologic method, the radiotherapeutic method of identifying tumors is effective and dependable only when applied by an experienced radiologist or radiologic clinician who has had this phase of radiology specifically in mind for a sufficiently long time to have acquired assurance.

In the majority of cases the history, the clinical features and the physical observations furnish more or less definite clues to the nature of the pathologic

process and to the organ or tissues primarily affected. In some cases, however, a high grade of clinical skill and extensive experience are required to solve what may appear as a complicated puzzle, but sometimes even then a measure of doubt may persist. It is at this point of uncertainty that the pathologist's report comes to solve the problem or to make the issue worse confounded. This depends on the ability and personality of the pathologist and on the training and faith of the clinicians who receive his report. If the pathologist has been trained to regard an embryonal carcinoma of the testis as a round cell sarcoma, and if the attending physician is not aware of the difference, the patient may pay for their ignorance with his life or with the loss of from several months to several years of useful activity. Or a patient's symptoms being chiefly or wholly abdominal, and yet not pointing clearly to any one organ or structure, a surgeon may be called and the patient may be subjected to an exploratory laparotomy when proper exposure of the abdomen to roentgen rays might, by causing the abdominal mass to diminish in size from 25 to 75 per cent in two or three weeks have proved it to be Hodgkin's disease or lymphosarcoma, and the patient might have been saved from an unnecessary operation. Or, if the pathologist cannot distinguish between diffuse endothelioma of bone and osteogenic sarcoma the patient may lose the chance of permanent cure which, though none too great at best, might result from well planned irradiation. In fact the exceptional radiosensitiveness of endothelioma of bone was one of the chief points that led Ewing to recognize this variety of neoplasm as belonging to a distinct group.

THE RADIOTHERAPEUTIC METHOD

The radiotherapeutic method is based on the well established fact that each variety of cell in the body has a specific sensitiveness or, rather, a specific range of sensitiveness to roentgen rays or radium. This is not intended to imply that all cells of one kind, such as lymphocytes or squamous epithelial cells, react at exactly the same rate and to precisely the same degree to a given dose of rays. A certain measure of variation in reaction must occur because different cells of the same kind are struck by the rays while in different stages of metabolism. Other still unknown factors also may play a part. However, if allowance is made for such variation, and if reaction time is taken as a criterion, the specific sensitiveness of each kind of cell looms up as the dominant single fact of radiology and deserves to be recognized as a law. And yet the existence of such a law and of its medical and biologic implications is not generally realized. For years much has been made of the dogma that pathologic cells are more radiosensitive than normal cells, but, as Lazarus Barlow and others have shown, the foundation on which this dogma rests is not as broad as one might infer. The notion that pathologic cells are more radiosensitive than normal cells of the same kind is valid only to the extent that the rate of mitosis of cells is affected by the pathologic disturbance. The significance of this factor, therefore, is limited to tumors and to processes of which cellular hyperplasia is an important feature. Such influence is small as compared with the specific natural susceptibility of each variety of cell and with the age or metabolic status of the cells. Although the factors responsible for such specificity have not yet been determined, the sensitiveness peculiar to each kind of cell appears to be related chiefly to the

natural life cycle. Thus the lymphocytes, the metabolic cycle of which among human cells is the shortest, are also the most radiosensitive, and the nerve cells the life cycle of which is the longest, are also the most resistant to irradiation. But to this question as to many others the final answer has not yet been given.

When, according to their radiosensitiveness, certain cells or groups of cells are exposed to a sufficient dose of roentgen rays or radium, the first perceptible effect is an alteration of or series of changes in the nuclear portion or genetic mechanism, of the cells. These changes are characterized collectively by arrest of mitotic division and by partial or complete degeneration of the cells, and individually by disorganization and fragmentation of the nuclear chromatin, vacuolar degeneration of the protoplasm, rupture of the cell and scattering of the fragments of chromatin from the nucleus among the remaining intact cells. The chromatin debris is then gradually absorbed by phagocytes (phagocytic reticular cells or macrophages), while the liquid portion of the degenerated cells, together with the ferments and antibodies which they previously contained, is liberated, becomes mixed with the tissue fluids, and ultimately finds its way into the blood. Moreover, if the time intervening between irradiation and perceptible reaction is taken as a criterion, it will be found that certain species of cells react more rapidly than others to a given dose, or that the degree of reaction to the same dose is greater for some kinds of cells than for others. According to present knowledge, cells may be classified, according to their radiosensitiveness, in the following order:

Lymphoid cells (lymphocytes)

Polymorphonuclear and eosinophilic leukocytes

Epithelial cells (1) basal epithelium of certain secretory glands, especially of the salivary glands, (2) basal epithelium (spermatogonial cells) of the testis and follicular epithelium of the ovary, (3) basal epithelium of the skin, mucous membranes and certain organs such as the stomach and small intestine, (4) alveolar epithelium of the lungs and epithelium of the bile ducts (liver) and (5) epithelium of tubules of the kidneys

Endothelial cells of blood vessels, pleura and peritoneum

Connective tissue cells

Muscle cells

Bone cells

Nerve cells

Thus, the epithelium of the skin stands about half way between the extreme radiosensitiveness of lymphocytes on the one hand and the comparatively great resistance of nerve cells on the other. Although the difference in susceptibility between the most sensitive and the least sensitive varieties of cells is considerable, none of the cells are wholly invulnerable to irradiation, all cells whatever their variety, may be destroyed or injured if exposed to a sufficiently large dose of rays, especially if doses within the therapeutic range are disregarded.

The difference in susceptibility between lymphoid and epithelial cells is sufficient to enable one to distinguish readily between the two. Whereas lymphoid cells are rapidly influenced by moderate irradiation and undergo more or less marked inhibition of mitosis and degenerative changes within from half an hour to three or four days, corresponding changes in epithelial cells are caused only by a much larger dose of rays and do not become apparent for a week or even longer. A tumor derived from squamous epithelial cells never undergoes clinically perceptible retrogression within one or two weeks after irradiation, whereas lymphoid

tumors usually begin to retrogress within from one to three days. The difference is so striking as to exclude all doubt. When such an example is presented to physicians who are unacquainted with the range of sensitiveness of different varieties of normal cells, they tend to assume that, as different tumors of the same kind vary somewhat in their susceptibility to irradiation, the difference might be accounted for in this way. But familiarity with the relative sensitiveness of cells and extended experience render such an explanation untenable.

As I have already intimated, such knowledge, by itself, can be applied effectively only to tumors derived from the more radiosensitive varieties of cells, but since its application may be both direct and indirect, the method may be of considerable value. To illustrate what is meant by direct or indirect application it is only necessary to mention a few examples. When the clinical and pathologic features of the patient's condition point to Hodgkin's disease or lymphosarcoma, and the response to irradiation confirms the clinical and pathologic features, this would be direct application of the method. But when the clinician or the pathologist, or both, regard the condition as one of carcinoma, but the reaction to roentgen rays indicates lymphoblastoma, this would be an indirect application of the method. Instead of direct and indirect, it might perhaps be better to speak of positive and negative applications of the method. At any rate, in tumors derived from radiosensitive cells, such as Hodgkin's disease, lymphatic or myelogenous leukemia, lymphosarcoma, embryonal carcinoma (often miscalled round cell sarcoma) and mixed, or teratoid, tumor of the testis, diffuse endothelioma (endothelial myeloma) and chondrosarcoma of bone, radiotherapy can almost always be depended on to furnish absolute diagnostic indications, irrespective of clinical or pathologic observations, so much so that on this ground alone, the experienced therapeutic radiologist can render valuable assistance in the diagnosis of obscure or doubtful cases. Moreover, if the clinical data, the physical observations and the rate of regression of the tumor or tumors should agree in indicating any of the conditions mentioned, the resulting diagnosis will be supported by necroscopic examination or, if not, the pathologist's interpretation will generally be found inaccurate.

By radiotherapy alone, the radiologist cannot distinguish between Hodgkin's disease and lymphatic leukemia or between the former condition and lymphosarcoma, but he can distinguish absolutely between any one of these conditions and any variety of epithelial or connective tissue tumor (carcinoma or sarcoma other than lymphosarcoma). He can distinguish lymphoblastoma from tuberculous adenitis. He can distinguish an embryonal carcinoma or a mixed (teratoid) tumor from tuberculosis of the testis. He can distinguish diffuse endothelioma of bone from chondrosarcoma or osteogenic tumor. In other varieties of tumor absolute distinction by radiotherapy alone is impossible, but correlation of the clinical, physical, roentgenologic and radiotherapeutic data may often settle the diagnosis without a biopsy or in the face of inconclusive or conflicting pathologic observations.

CASE 1.—A man aged 36 who registered at the Mayo Clinic May 6 1924 had been well until November or December 1923 when he began to suffer from a dull ache in the upper right abdominal quadrant. The pain was not constant and often radiated to the right groin and testis. He had been able to work steadily in spite of it. Besides hemorrhoids a thorough

examination failed to disclose the cause of the pain. Internal and external hemorrhoids were ligated and excised, May 15, 1924, but this did not influence the abdominal pain, which continued, although a little later it shifted to the right lower quadrant of the abdomen. In May, 1927, a rather indefinite mass was found in the left epigastric region, and in January, 1928, the mass had become more definite, had increased in size and additional symptoms, including gas distention after eating, developed. An exploratory laparotomy was performed, Feb. 4, 1928, and the surgeon found a tumor which to him, appeared to be carcinoma of the pancreas. A specimen from the tumor was examined microscopically, and the pathologist reported it as carcinoma, graded 4.

Between February 20 and 28, the patient was given a course of roentgen irradiation to the entire abdomen from front and back, through eight fields. This was followed by prompt regression of the abdominal tumor and by correspondingly rapid improvement in his condition. By April 11 he had gained 15 pounds (68 kg) and was much stronger. Except for a slight, occasional pain around the incision the abdominal symptoms had disappeared, but a node in the left submaxillary region had become sufficiently large to attract the patient's attention.

After a second course of treatment, given between April 11 and April 16, 1928, the abdominal tumor and the symptoms disappeared completely. In November, 1928 the condition of the abdomen was normal, but lymph nodes in the right occipital, cervical and submaxillary regions, as well as in both axillae, were found enlarged. The nodes diminished rapidly soon after the neck and axillae were treated. From December 1928, until February, 1933, the patient's condition fluctuated. At times fresh lymphadenopathy in the neck and elsewhere developed, but under treatment this subsided and disappeared for long periods, to reappear later. The condition of the abdomen was satisfactory for some time. Later, however, evidence of fresh lymphoid hyperplasia became apparent but disappeared after irradiation. It was necessary to treat the patient at intervals of from one to six months. Early in 1933 his general condition deteriorated perceptibly and he died, Feb. 20, 1933.

The rate of regression and of general improvement was characteristic of lymphoblastoma and quite different from the slow partial regression sometimes observed after radiotherapy directed against an epithelial tumor. So characteristic was the rate of regression that the assumption of carcinoma of the pancreas had to be discarded, it was obvious that the patient was suffering from lymphoblastoma, probably beginning in the retroperitoneal nodes. If, at the beginning of his illness, the symptoms had been due to carcinoma, it is hardly likely that he could have lived five years. On the other hand, the initial response of the abdominal tumor to irradiation, and later the appearance of lymphadenopathy in the neck, axillae, groins and even the mediastinum, clearly showed that the process was lymphoblastomatous and not carcinomatous and confirmed the indications furnished by radiotherapy, which in this case could not be reconciled with the pathologic diagnosis of carcinoma.

CASE 2—A woman, aged 37, who registered at the clinic, Feb. 13, 1933, had noted the onset of urticaria, pain around the posterior aspect of the right hip, radiating down the right lower extremity, and a sense of pressure in the back and around the rectum, six or eight weeks before. A gynecologist had inserted a pessary which the patient was still wearing. Another physician had injected varicose veins around the anterior aspect of the right thigh. Four weeks after the onset of symptoms (four weeks before her registration at the clinic), a mass had been found in the epigastric region, and the patient had been subjected to an exploratory laparotomy which had disclosed a tumor infiltrating the mesentery. A specimen obtained by the surgeon was submitted to pathologists, who accurately interpreted the tissue as lymphosarcoma.

Between Feb. 13 and Feb. 21, 1933, roentgen treatment to the upper half of the abdomen was followed by rapid regression of the abdominal masses and by corresponding improvement in

the patient's condition. The rate of regression was absolutely characteristic of lymphosarcoma. A second course of treatment between April 17 and April 20, 1933, was followed by additional and equally rapid improvement. By March 14, 1933, the abdominal lymphadenopathy had diminished 60 per cent in size, and the patient's symptoms had completely disappeared.

This case is cited merely to show that the diagnosis could have been arrived at with equal accuracy without operation, merely by exposing the abdomen to roentgen rays in the proper manner. Irrespective of the pathologist's report, the history pointed to retroperitoneal lymphadenopathy as the cause of the patient's symptoms. If the physicians who had examined her previously had had experience with radiotherapy, the operation to which the patient had been subjected would not have been necessary. Exposure of the upper two thirds of the abdomen to roentgen rays of medium wavelength, through two anterior and two posterior fields, with the four beams of rays converging on the prevertebral nodes, would have been sufficient to establish the diagnosis within two weeks.

CASE 3—A woman aged 56, who registered at the clinic, March 1, 1933 had been well until three years previously when she had noticed, in the epigastrum, a mass the size of a large orange. Her impression was that the size of the tumor had remained about the same for six months or longer and the growth then gradually disappeared. In the fall of 1932 the epigastric tumor reappeared and gradually increased in size. Also the abdomen became more and more distended. During the few weeks prior to her coming to the clinic the epigastric mass had grown rapidly, had caused pressure symptoms and had been accompanied by shortness of breath, but at no time had the patient suffered from pain.

The abdomen was moderately distended and contained fairly large softish masses in the epigastric and umbilical regions as well as in the left iliac region. The peritoneal cavity and both pleural cavities contained a small quantity of fluid. March 3, 1933, a diagnostic aspiration of the right pleural cavity was performed, and 1250 cc of thick milky fluid was withdrawn. Some of the fluid was used for culture, some for guinea pig inoculation, and some for determination of chyle. Evidence of tuberculosis could not be obtained, but it was definitely established that the fluid was chylous in character.

A course of roentgen treatment was given to the upper two thirds of the abdomen and to the entire thorax between March 6 and March 14, 1933. This caused rapid regression of the abdominal masses and equally rapid diminution in the intrathoracic fluid. The cough and dyspnea also subsided rapidly. The rate of regression was exactly what would be expected in lymphoblastoma and thus confirmed the clinical impression. Regression of the abdominal tumors continued during the ensuing few weeks and all the patient's symptoms disappeared.

In spite of the circumstances mentioned, the general condition of the patient throughout her illness had remained relatively good, especially if the duration of the illness and the physical observations were taken into account. The patient's impression that the abdominal tumor had disappeared spontaneously about six months after its initial appearance must not be taken literally but merely indicates that the mass or masses diminished in size sufficiently to give the patient the impression that they had vanished. It is well known that certain varieties of tumor vary in size from time to time, and sometimes such variations are sufficient to give a patient the impression that the tumor has disappeared when it actually has not. Clinically, it seemed obvious that the pathologic process had started in the para-aortic lymph nodes around the celiac axis, just below the mouth of the thoracic duct, through which it had extended upward and had blocked the duct in the thoracic portion of the posterior mediastinum, causing

chylous fluid to accumulate in both pleural cavities. Under the circumstances, the natural assumption was that the patient had lymphoblastoma. If radiotherapy had not been used for differential diagnosis in this case, it is possible that the patient would sooner or later have been subjected to an operation, which would have been essentially useless as far as the patient was concerned.

In contrast with different forms of lymphoblastoma, tuberculous processes respond much more slowly to irradiation, and complete regression usually requires that the affected region be exposed to the rays at regular intervals for from three to twelve months, or even longer. The difference in radiosensitivity between lymphoblastomatous adenopathy and tuberculous adenitis is so great as to leave no room for doubt. Significant and valuable as this point may be in relation to enlarged nodes in superficial parts, such as the neck, it is of still greater value when the enlarged nodes are situated in the mediastinum, where the clinical features tend to be less distinctive and where a biopsy cannot help the clinician out of his dilemma. The following is a case in point.

CASE 4—A woman aged 53, who registered at the clinic, March 8, 1928, had noticed for six or seven years that her heart missed an occasional beat at night and that this interfered with sleep. Thenceforth she had attacks of vertigo and fatigue, from which she could obtain relief only by lying down. Her pulse rate had been more or less steadily elevated, but electrocardiographic examinations in 1927 had not disclosed any definite disturbance in the cardiac rhythm. During the month preceding registration the right side of the neck had swelled and become sore and a slightly enlarged node adjacent to the right sternomastoid muscle had become palpable. This was accompanied by occasional soreness on the right side of the neck. It seemed most likely that, since the tonsils and one tooth had been infected for some time previously, the slight cervical adenitis might have resulted from such infection. Accordingly, she was advised to have the tonsils removed and the tooth extracted. Tonsillectomy was performed April 4, 1928 and these glands showed chronic inflammation, fibrosis, pus and ulceration in the crypts. Subsequently the soreness on the right side of the neck increased, the enlarged nodes on this side did not recede, and other nodes on the same side also enlarged.

May 21, 1931 pus was evacuated from some of the enlarged nodes on the right side of the neck were removed surgically, and microscopic examination showed these nodes to be tuberculous. A roentgenogram of the thorax May 18, 1931 showed circumscript broadening of the upper mediastinal shadow. This was assumed to be due to enlarged mediastinal lymph nodes and the previous history made it seem likely that these nodes were tuberculous. On this assumption roentgen treatment was instituted, the patient receiving the first course between June 29 and July 1, 1931. The treatment was directed to the mediastinum and to both sides of the neck. A second course of treatment was given between July 27 and July 29. By this time the condition of the patient had improved considerably, the lymph nodes in the neck had almost disappeared and a roentgenogram of the thorax Aug. 24, 1931 showed substantial retrogression of the enlarged mediastinal nodes. Moreover the rate of such regression confirmed the clinical and roentgenologic assumption of tuberculous mediastinal adenitis. Additional courses of treatment were given between Aug. 24 and Aug. 26, Sept. 21 and Sept. 22 and on Dec. 7, 1931, when the roentgenologic appearance of the thorax was normal and the enlarged nodes in the right side of the neck had disappeared. The patient's condition has been entirely satisfactory since that time. An interesting point also is that the tendency of the heart to miss an occasional beat, the abnormally high pulse rate and the undue tendency to fatigue have disappeared and the patient is well.

In this case it is true the character of the enlarged nodes in the neck made it seem most likely that the mediastinal adenopathy also was tuberculous. Still the

clinical and roentgenologic features were not sufficient to remove all doubt, but the response to irradiation cleared away all uncertainty. Of course, if the tuberculous process in the mediastinal nodes had undergone calcification, radiotherapy could not have had the same effect.

Radiotherapy may also enable one to distinguish embryonal carcinoma and mixed, or teratoid, tumor of the testis, whether in their primary site or in their most common, abdominal or supraclavicular, sites of metastatic dissemination, from other kinds of neoplasm with which they may sometimes be confounded. Being derived from the spermatogonial cells, embryonal carcinoma (not adenocarcinoma) of the testis is just as radiosensitive as the parent cells of the normal testis which rank next to the lymphoid cells and to certain mucus-secreting epithelial cells (salivary glands) in their susceptibility to roentgen rays and radium. The sensitivity of mixed, or teratoid, tumors is sometimes as great and apparently depends on the proportion of spermatogonial epithelium entering into their composition.

In bone tumors, also, radiotherapy often furnishes invaluable diagnostic indications. As pointed out by Ewing and as I have recently emphasized, the susceptibility of solitary endothelioma of bone to roentgen rays or radium is so pronounced and so characteristic as, by itself, to constitute a most valuable means of differentiation. As a class, bone tumors derived from cartilage are, in respect of their susceptibility to roentgen rays or radium, intermediate between the solitary endothelioma and the osteogenic sarcoma, but the difference between chondrosarcoma and endothelioma is greater than the difference between chondrosarcoma and osteogenic sarcoma. By sufficiently intense irradiation chondrosarcoma can be made to retrogress perceptibly and sometimes to a considerable degree for a limited period of time (weeks or months), but, as in osteogenic sarcoma, complete and permanent disappearance of such a neoplasm is rare. Nevertheless, such retrogression as does occur usually proceeds at a more rapid rate, is more pronounced and lasts somewhat longer than in the osteogenic tumor. In most cases the difference in radiosensitivity between these three types of neoplasm is sufficient to distinguish them clearly irrespective of clinical, roentgenologic and pathologic indications. Of course, when the results of radiotherapy support the clinical, roentgenologic or pathologic observations, the weight of evidence becomes overwhelming.

CASE 5—A boy aged 16 years who registered at the clinic, Dec. 1, 1932, had always been well until four months previously when he noticed a dull, intermittent ache around the anterior aspect of the lower third of the left thigh. Except that while baling hay during the summer he had used this thigh to assist in loading the bales neither he nor his father recalled any injury to which the pain could be attributed. Gradually the pain had increased in severity and become more constant. At no time had the patient been aware of fever and his weight was normal. During the previous two or three weeks slight swelling of the lower part of the left thigh had become apparent but the color of the overlying skin had remained normal. Walking had not been affected appreciably and the boy had been able to ride a horse for five miles daily on his way to and from school, but running caused the pain to increase. The function of the joints had not been disturbed.

Examination disclosed slight widening of the lower part of the left thigh which measured 1.5 cm. more than the right thigh, also tenderness and slight limp on walking. Roentgenograms showed diffuse widening of the lower third of the left femur with concentric deposition of new bone in the periosteum and decrease of central density. These features were

regarded as representing solitary diffuse endothelioma (Ewing). Evidence of intrathoracic metastasis could not be found. The "onion skin" appearance of the left femur at the level of the tumor was so classic that even the orthopedic surgeon did not hesitate to regard the tumor as endothelioma. To the surprise of every one, however, microscopic examination by Broders of tissue removed from the tumor, Dec 4, 1931, brought the report of "osteogenic sarcoma (graded 2), differentiating for the most part in the direction of cartilage."

If the tumor should react to irradiation like true osteogenic sarcoma or like chondrosarcoma, the onion skin appearance of the new bone as an indication of endothelioma would have to be disregarded. On the other hand, if the growth should perchance retrogress at the rapid rate so characteristic of Ewing's endothelioma, the pathologic interpretation would have to be revised.

The father having refused to consider amputation between Dec 7 and Dec 9, 1931, the region occupied by the growth was irradiated with six beams of rays of medium wavelength (generated at 135 peak kilovolts and filtered through 6 mm of aluminum). The pain which previously had been rather severe diminished rapidly. The tumor also retrogressed but the rate of regression was that of chondrosarcoma rather than endothelioma. Between Dec 31, 1931, and Jan 2, 1932, the patient was given a second course of treatment. When he returned, February 16, he was free from pain and the tumor had retrogressed further but it was clear that the neoplasm was not an endothelioma. A third course of treatment was given between February 16 and February 17. Roentgenograms April 7, 1932, indicated slow but continued improvement in the condition of the left femur. The patient was allowed to go home without treatment but was instructed to return in three months. Before this interval had elapsed the father wrote that the pain had reappeared and was increasing, and that the lower half of the left thigh was swelling again. Amputation was again advised, but the father again refused to follow this advice. Therefore another (fourth) course of roentgen treatment was given between June 30 and July 1, 1932. The pain abated and the swelling appeared to subside for a short time and roentgenograms, July 21, revealed definite recession of neoplastic activity, but it was obvious that parts of the growth were still active.

When the situation was again discussed with the father he finally consented to amputation which was performed by Dr F. C. Thompson, at St. Joseph, Mo. A large specimen of the tumor from the amputated limb, furnished by Dr Thompson was subjected to microscopic examination by Dr Broders, who described the growth as follows: "This neoplasm, which is of a low grade 2 malignancy, belongs to the general class of osteogenic sarcoma, however, while there is some tendency to bone formation, its cells for the most part are differentiating into cartilage of a more or less atypical nature. In the undifferentiated areas, one sees practically normal cartilage cells, however, in these areas also there are a few cells with large, irregular, hyperchromatic nuclei and in which the amount of cytoplasm is abnormally large."

The significant points are that a tumor of the femur, with features apparently so characteristic of the solitary diffuse endothelioma described by Ewing, should have failed to react to roentgen rays in the manner and at the rate peculiar to tumors of this kind, that its radiotherapeutic behavior and its pathologic features should so absolutely and conclusively have concurred in establishing its essentially cartilaginous character, and that in this case, as perhaps in other cases, the laminar deposition of new bone in the outer layers of the neoplasm, or so-called onion-skin effect, should have proved unreliable and actually misleading as a diagnostic sign. The response of the tumor to repeated and intense roentgenization corresponded in all respects to the usual reaction of malignant tumors derived from cartilage, distinctly more radiosensitive than true osteogenic sar-

coma and much less sensitive than Ewing's solitary endothelioma, it furnishes additional evidence, if such were needed of the great value of irradiation as a means of distinguishing different varieties of tumor.

If space were available, many other examples of the practical value of radiotherapy as a means of identifying certain varieties of tumor could be cited. All if pathologists and others were familiar with the relative radiosensitiveness of different kinds of cells, such knowledge would undoubtedly furnish data that would prove significant for purposes of classification. Indeed it is safe to say that, as internists, surgeons and radiologists acquire experience and become familiar with the relative radiosensitiveness of neoplasms, there may be a tendency toward excessive dependence on the method. Also it is certain that when a greater number of pathologists come to realize the significance of the specific range of sensitiveness of different varieties of cells, this fundamental law may help to solve certain problems in cellular physiology, histology and pathology which until now have remained insoluble.

ABSTRACT OF DISCUSSION

DR NOBERT ENZER, Milwaukee. It is not appreciated often enough that the submission of a small piece of tissue to the pathologist places on him a considerable responsibility. The pleomorphism of tumors is perhaps the greatest danger. The classification has been rather confusing and an understanding of the primary cell origin is needed. Cells may be and indeed are multipotential and develop different types of tissue under different stimuli. For example, lymphoblastomas and connective tissue tumors are derived from mesenchyme. It is important that the purely descriptive form of classification be discarded. As Dr Desjardins mentioned it is important that physicians learn to separate the granulomas that have peculiar features, clinically resembling neoplasms but pleomorphic in their cell structure. Such lesions probably do not take origin from a single stem cell. I am referring particularly to Hodgkin's granuloma. In the interpretation of x-ray sensitivities a differentiation should be made between tumors that are unicentric, if I may use the term, or local in origin as opposed to those which are polycentric or systemic in origin. I am referring to certain types of lymphoblastoma that arise spontaneously in several depots in the body, as opposed to lymphoblastomas that arise, for example in the cervical region or other lymphoid depots. While sarcoma of the testis does occur the great majority of malignant tumors of the testes are embryonal carcinomas. Such tumors take origin from primitive germ layers. Sarcoma of the testicle is usually a lymphosarcoma. It is possible that these tumors take origin in primitive mesenchyme in which the lymphogenic tissue is abnormally stimulated or developed. In other words, these tumors, sarcoma of the testes while morphologically lymphogenous, may in reality be properly classified as embryonal carcinoma.

DR A. U. DESJARDINS, Rochester, Minn. I am very grateful to Dr Enzer for his remarks. I should be the last man to cast aspersions on the pathologist. What I meant to bring out was that the radiosensitiveness of tumors is becoming a valuable point in diagnosis but on condition that the interpretation is done by some one who not only has had adequate experience but whose mind has been focused on this particular point long enough to develop assurance. I realize the danger of any one without sufficient experience and without having his mind specifically on the point attempting to do it because not only will he get into trouble but he will get others into trouble, including the patient. So far as the diagnostic value is concerned radiotherapy has both a positive and a negative value and therefore a double value, because it enables one not only to recognize a suspected lymphoid tumor but also to exclude other tumors when a lymphoid tumor is suspected, and vice versa. As applied to tumors of bone, radiotherapy makes it possible to distinguish endothelioma from chondrosarcoma and also chondrosarcoma from osteogenic sarcoma. In an occasional case special difficulties may be encountered but these are exceptional.

RELATIVE MERITS OF SPINAL AND
ETHER ANESTHESIAHAROLD L FOSS, MD
AND
LESLIE J SCHWALM, MD
DANVILLE, PA

Surgery involves many controversial subjects which add interest to medical discussions and zest to meetings whenever doctors get together. Spinal anesthesia is a recent example, for no method has had stronger partisans ready to defend, on the one hand, or to condemn, on the other. As has been the case with most surgeons, we have been greatly interested in the question of the relative merits of this anesthetic and anxious to know the truth of the matter. On finding recently that sufficient material from which to draw conclusions had accumulated in our own clinic, we attempted to determine the nature of our own results. With no analysis having been made at the time and, therefore, without bias, we offered to read a paper entitled "The Relative Merits of Spinal and Ether Anesthesia" before this section and so, with an open mind and with no attempt at prophesying what our conclusions would be, we set about making a comparative study of the results following the use of the two forms of anesthesia, ether and spinal, in a series of operations performed under closely similar conditions.

It was with a sincere desire to determine the actual facts pertaining to the relative safety of spinal and ether anesthetics and with a resolve to steer a middle course between immeasurable enthusiasm, on the one hand, and unjustified condemnation, on the other, and to rely only on carefully collected data, that the study was made. The investigation was carried out on a series of major procedures all performed by one of us (H. L. F.), except for a few performed by an assistant, in the same hospital and operating room and with the same personnel, 4,000 consecutive operations were performed, one half under ether anesthesia and the remaining half under spinal anesthesia. By ether anesthesia we refer to ether, or ether plus nitrous oxide or ethylene, but in which no spinal anesthesia is used, by spinal anesthesia, subarachnoid injection of procaine hydrochloride supplemented in a few cases by nitrous oxide and ethylene. Every anesthetic was administered by one of three trained anesthetists who had devoted many years exclusively to this work and who, therefore, were experienced and skilled. We have not resorted to spinal anesthesia in closed fracture reduction, hence, no such cases are included, while such procedures as cystoscopic examinations and other similar minor procedures, occasionally performed under spinal anesthesia are, of course, not listed. All the procedures herein described come well within the category of major operations (table 1).

The operations whether with ether or spinal anesthesia, were all consecutive and were all performed on structures below the diaphragm. Since the types of operation and the lesions for which they were performed were about equally divided between the two anesthetic methods the study is fair and comparable. It seemed therefore, that a review of the anesthetic results, the patient's reaction and condition during and after the procedure with especially, a comparative

analysis of the mortality figures in these two closely paralleled lists of operations, would cast an interesting light on the relative merits, advantages and dangers of the two anesthetic agents.

Safety in an anesthetic, as all will agree, is of the first importance, and while we appreciated the manifold advantages of spinal anesthesia, yet we realized that it possessed certain inherent dangers. How great were these dangers? Were they actually greater than those possessed by ether and, if so, in what degree, and were they of sufficient moment to contraindicate our continuance of this method of producing insensibility to pain? These questions first arose when, after several hundred spinal anesthetics, we had a sudden and inexplicable death occurring several days postoperatively. Because of this fact, for a time, spinal anesthesia was discontinued when, most unexpectedly another death occurred, but this time with ether, a death equally difficult to account for. This recalled to mind Lundy's¹ careful analysis of a large series of operations under ether, performed at the Mayo Clinic, which clearly showed that even accompanying ether there is, not infrequently, a concealed and delayed mortality, a fact often disregarded, especially by those who are opposed to spinal anesthesia. It has been our

TABLE 1—Classification of 4000 Operations Under Ether and Spinal Anesthesia

Operations	Ether	Spinal
Amputations	26	29
Appendectomies	458	449
Exploratory laparotomies (chiefly for carcinoma)	123	103
Herniorrhaphies	217	281
Operations on bones and joints	29	21
Operations on gallbladder and ducts	366	310
Operations on kidney bladder and prostate	50	115
Operations on pelvis	477	412
Operations on stomach and intestines	133	230
Open reduction of fractures	27	23
Splenectomies	4	2
Miscellaneous	70	60
Total	1,000	2,000

observation, as it has been Pemberton's,² that there is a tendency for the surgeon to attribute to the anesthetic or its mode of administration any unusual complication which cannot readily be accounted for otherwise."

In our experience an occasional remote death, occurring a week or two postoperatively and in certain cases, impossible to understand, occurred following spinal anesthesia, but, as has been stated, they also occurred following the use of ether. As some one has said, it is our business to see that our patients leave not only the operating room alive but the hospital as well, and the patient is just as dead when he dies three weeks postoperatively as he is when he dies on the operating table. Much of the extensive literature on the subject was read, but it finally appeared that no personal conclusions could be drawn, in spite of the widespread claims for and against spinal anesthesia until a sufficient number of patients had been operated on in our own clinic and the results carefully analyzed.

Although spinal anesthesia greatly facilitates the work of the surgeon the question arises. Does this most desirable advantage offset the anesthetic's alleged dangers if dangers it has, and should the method be reserved only for those cases in which technical facility

(May 17) 1935.

is of transcendent importance? Can it with safety, comparable to that of inhalation anesthesia, be used more or less as a routine measure in operations below the level of the diaphragm? If this is true, but few of us who have had much experience with spinal anesthesia would wish to use anything else, so satisfactory is it. And so it was with these and many other closely associated questions in mind that the study was undertaken.

The mortality figures for the series do not, of course, represent those of our surgical service as a whole, they are considerably higher, as should be made clear, owing to the fact that all the serious abdominal operations are included, and the operations performed on the thorax, head and neck, when the anesthetic has been local or gas or a combination of these, and operations carrying lower mortality figures than the more formidable operations in the abdomen are excluded. Moreover, in a medical center serving a widespread rural territory, it is obvious that surgical disease is of a more serious nature when first seen at the hospital than in the city institutions where physicians' offices and hospital dispensaries are readily accessible and where the patient becomes accustomed to resorting to them promptly. The rural patient is apt to keep his complaints long to himself until finally driven to seek relief, this fact having been noted by all who work in clinics serving far-flung rural sections. As an illustration a fifteen years' average shows that our patients with acute appendicitis are admitted seventy-two hours after the onset of symptoms, patients with carcinoma of the colon, thirteen months after. These points are merely made in extenuation, if it is necessary, for the mortality figures appearing in the paper.

POSTOPERATIVE DEATHS WITH SPINAL ANESTHESIA

Authors writing in defense of spinal anesthesia have frequently stated that they have had no deaths which, to use their expression, "by the widest stretch of the imagination, could be attributed to spinal anesthesia",

or that there were "no deaths for which the anesthetic could possibly be blamed" or that "in a series of one thousand cases there was but one death the result of the anesthetic." Almost invariably, because they fail to list all their deaths they afford the reader no opportunity to draw his own conclusions. Such methods of case reporting are incomplete and occasionally misleading. This fact being recognized and also realizing that deaths occurring several days following the administration of an anesthetic may rightfully be attributed to an untoward action of it, we recorded every death occurring in the hospital, it being the only fair and

unbiased way of arriving at a true appraisal of the relative safety of the two anesthetics under consideration (table 2).

In 1,875 cases, Sise³ reported 4 deaths occurring on the operating table within one hour of the injection of a spinal anesthetic but called attention to the undeniable fact that sudden fatalities have occurred in many instances following the use of ether as well. Muller and Overholt⁴ reported 2 sudden deaths soon after

* Two thousand operations under ether anesthesia in 2,000 operations under spinal anesthesia in

operation in 533 cases 1 occurring on the operating table. In McKittrick, McClure and Sweet's⁵ series of 338 patients there were 40 deaths a mortality of 11.8 per cent 1 death only being attributed to spinal anesthesia, yet there were 6 unexplained sudden deaths all occurring in the first forty-eight hours. In none of these was the fall of blood pressure remarkable.

Undoubtedly many deaths attributed to other causes have occurred from the use of the anesthetic but it is equally true that many deaths have been falsely attributed to spinal anesthesia and in many of these cases postmortem examinations showed that conditions were present which would have caused the patient's death irrespective of the anesthetic used. We believe however, with Bower and his associates⁶ "that the death of a patient whose blood pressure drops more than 50 per cent or who develops respiratory embarrassment within twenty minutes following the injection and who does not react to within 25 per cent of the normal before the operation is finished and subsequently develops secondary shock and dies is an anesthetic death whether on the operating table or in the recovery room."

Not only must respiratory paralysis be guarded against, but when the anesthetic reaches the fifth or sixth thoracic nerves, especially if in a relatively high concentration and particularly with patients with damaged myocardiums death from two to six days following the operation may occur and may seem difficult to explain. We believe however, that spinal anesthesia has been too frequently used in unskilled hands.

and that this fact accounts for most of the unfortunate results so often reported. However, in our studies, the mortality rate in our hospital was no greater with spinal anesthesia than with ether, deaths in the first, second, third, fourth and fifth day periods being considerably greater in number in the series in which ether anesthesia was used (table 3).

PERSONAL PREJUDICES

Surgeons have been too greatly influenced by strongly opinionated authors who, obviously prejudiced, have written either supporting or condemning the use of spinal anesthesia. A host of papers has appeared citing long and fortunate experiences with spinal anesthesia with no deaths "attributable to the anesthetic," a phrase leaving a justifiable doubt in the mind of the reader. Tendler recently presented a tabulation embracing a large variety of techniques and drugs and including a series of 6,000 cases of Rastichs with "no

TABLE 4—Deaths in Operating Room

Ten Patients Who Died in Operating Room under Ether Anesthesia (From a Total of 2,000 Consecutive Operations)		
Patient	Age Years

deaths", one by McCormack of 5,000 cases with "no deaths", one by Gosset and Mounod of 2,000 cases with "no deaths", one by Bainbridge a series of 1,065 cases with "no deaths" and one by Labat of 1,000 cases with "no deaths". By this we are led to believe that there were no deaths the authors were willing to attribute to the method consequently, the personal equation and that psychological phenomenon of "the will to believe" render such data of questionable worth.

Per contra innumerable papers have appeared unalterably opposed to spinal anesthesia many of their authors being as was recently the case with a distinguished writer who summarily condemned spinal anesthesia surgeons who have never used it and whose knowledge is therefore entirely second hand. Obviously such opinions are anything but authoritative and are as valueless as those cited in the preceding paragraph.

DEATH IN THE OPERATING ROOM

While death in the operating room is referred to in many published reports as an accident to be occasionally, possibly frequently, expected when spinal anesthesia is employed, in our series of 2,000 operations performed under spinal anesthesia we witnessed it but once, yet saw it occur ten times with ether anesthesia (table 4). In other words, in this series of 4,000 operations, deaths on the operating table occurred 90 per cent less frequently when the patients were operated on under spinal anesthesia. We may add, all the inhala-

tion anesthetics were administered by skilled anesthetists and the deaths on the operating table in the ether series occurred during operations on desperately ill or injured patients obviously exceedingly bad risks. There were however as many equally unpromising patients operated on under spinal anesthesia, with the marked decrease in mortality referred to previously, a strong argument at least in our experience, for spinal anesthesia and for its use in certain cases in which the patient is a bad operative risk. Operations following which death occurred are listed in table 5, and the

dosage of procaine hydrochloride in table 6 The cause of all deaths in the hospital both with spinal anesthesia and with ether is shown in table 7

We are passing through a period of widespread lack of understanding regarding spinal anesthesia largely due to the lack of a standardized method and a perfected technic Dill⁹ recently inquired

What is the best drug to use? Novocaine, neocaine, spinocaine, tutocaine, nupercaine, stovaine, apothesine? Should the solution be heavy or light, ready made or extemporized with the patient's own spinal fluid? Should it be injected with much, little or no barbotage, slowly or rapidly? Should the patient sit up or lie down for the injection? Some carefully measure the spinal pressure, tilt the table according to the tiltometer, inject adrenalin, ephedrine or caffeine, before, during or after Others care for none of these Some claim that adrenalin and ephedrine are not only useless, but even harmful Koster and Labat, to forestall cerebral anemia, insist upon the Trendelenburg position Evans recommends raising the shoulders on two pillows to forestall diffusion cephalad Most would not apply it to operations above the diaphragm, others apply it to the head, neck and thorax as well How should we gauge the dose? Some say by body weight, others say by size of the spinal canal and the amount of spinal fluid, and estimate the amount by "experience" Is the height of analgesia controlled by volume of spinal fluid aspirated and reinjected, dose of drug, or injection time? May deny that there is any control

Briefly, we would answer these questions by saying that procaine hydrochloride is the best drug to use It should be dissolved in an ampule in the patient's spinal fluid, then injected slowly, with some barbotage, depending on the extensiveness of the anesthesia desired The patient should be sitting up or lying on his side while the injection is being made, and placed in the horizontal position thereafter or in the Trendelenburg position if the surgeon is to operate in the pelvis The dose

should range from 25 to 200 mg, but only occasionally the latter (table 8) Tilting the table a few degrees one way or the other is of no especial assistance Epinephrine and ephedrine are helpful Operations should be confined to structures below the diaphragm We agree with Stout¹⁰ and with McKittrick and his associates¹¹ that the level of anesthesia depends largely on the amount of fluid used to dissolve the crystals, and that the position of the patient, if fairly large dilutions are used, has but little to do with it We also feel that, after the first few minutes, the level cannot be changed

No one will deny that spinal anesthesia greatly facilitates the work of the surgeon but, also, from the personal point of view of most patients, the method possesses distinct advantages, as is shown in table 9

PULMONARY COMPLICATIONS

In every essay on spinal anesthesia the question of postoperative pulmonary complications invariably appears Campbell¹¹ stated that such conditions are several times more frequent under inhalation anes-

thesia, yet many have reported a greater incidence with spinal anesthesia Our experience, as well as that of many writers, suggests an incidence about equal with the two forms, possibly even greater with spinal anesthesia, and this result coincides with that of McKittrick, McClure and Sweet who compared the pulmonary complications in two surgical series, one in which spinal anesthesia was used and the other inhalations

It seems, therefore, that we cannot hope to reduce the incidence of postoperative pulmonary complications by using spinal anesthesia, however great some of its advantages in other directions may be Many authors have reported a higher incidence of these conditions and, especially, postoperative pulmonary atelectasis, including Brown and Debenham,¹² Foss and Kupp,¹³ and Muller and Overholt⁴ The inhibition of the force and depth of respirations with a resulting increased difficulty of ridding the bronchial tree of foreign matter or secretions probably accounts for this In this series, however, there were 11 deaths from pneumonia in 137 deaths following ether and but 13 from pneumonia in 140 deaths following spinal anesthesia

SPINAL ANESTHESIA IN ACUTE ABDOMINAL EMERGENCIES

With certain conditions it seemed that spinal anesthesia is definitely helpful in reducing the mortality rate In our first 400 operations for acute appendicitis performed under spinal anesthesia, the mortality was exactly 33 per cent less than that in the preceding 400 operations performed under ether The series may be too small to be significant, but as similar reductions invariably occurred in operations for perforated ulcer, for strangulated hernia and for acute intestinal obstruction, we were convinced that, at least with acute abdominal emergencies, the far greater ease and celerity with which the operation can be performed clearly exerts a positive influence in reducing the operative mortality

EFFECTS ON THE SPINAL CORD AND
MENINGES

Since surgeons first began using spinal anesthesia there have been speculations as to the effect of the drugs used on the spinal cord and meninges Spielmeier,¹⁴ in 1908, produced, experimentally, peripheral degeneration of the myelin in the lateral, anterior and posterior columns of the spinal cord without changes in the nerve roots or nerve cells Lundy recently produced the same change by using huge doses of procaine hydrochloride Transient lesions of the spinal cord have been reported by Davis, Haven, Givens and Emmett¹⁵

In the 2,000 cases studied by us and in nearly 1,000 injections made since the material for this paper was gathered, we have never seen the slightest evidence of peripheral neuritis or sensory or motor disturbances We have never seen a case of foot drop or have had patients who suffered from pain in the body or in the legs following spinal anesthesia

Lundy, in a personal communication, stated that at the Mayo Clinic they have never noticed that sterile procaine hydrochloride, administered by the usual technic and in safe doses, has produced any serious changes in the spinal cord

CONCLUSIONS

1 Mortality figures, based on all deaths in the hospital following 4,000 consecutive major operations, one half performed under spinal anesthesia and one half under ether, have been studied

2 Deaths in the operating room, as has frequently been alleged, are by no means more frequent with spinal anesthesia than with ether In fact, in this series, they were far commoner with ether, in a proportion of 10 to 1

3 Postoperative deaths occurring in the first few days following operation are not, as is frequently claimed, more common after spinal anesthesia In this study the reverse was true, ether carrying a much higher mortality rate

4 The ultimate death rate in the hospital is practically the same following the administration of the two anesthetics In this series of 4,000 closely parallel operations the difference was only 0.15 per cent

5 While pulmonary complications are no less common following spinal anesthesia, there is not a noteworthy increase in the incidence of pulmonary deaths when this anesthetic is used over those occurring following the administration of ether In this series the number of deaths due to postoperative pulmonary complications was practically equal with the two methods

6 Spinal anesthesia can be used more or less as a routine measure in operations below the diaphragm with far greater relative safety than most surgeons at present seem to believe It is the anesthetic, *par excellence*, in most acute abdominal emergencies, acute appendicitis, intestinal obstruction and perforated ulcer

7 A large number of papers have been written opposed to, or in support of, spinal anesthesia and contain conclusions which are based on unsupported opinions rather than on a thorough, comparative analysis of hospital morbidity and mortality and, therefore, are not only far from being helpful but have been, frequently, misleading

8 There is some evidence to suggest that certain changes in the spinal cord may follow the injection of procaine hydrochloride into the subarachnoid space, but we are yet to learn whether or not this is common, is permanent or is of any especial significance, provided an aseptic and proper technic is observed

9 Improvements in technic have rendered the use of spinal anesthesia as safe as the use of ether anesthesia, and, in most instances, it is infinitely more convenient and helpful and followed by fewer complications

10 The majority of patients prefer spinal anesthesia, this being especially true with those who have had both spinal and ether anesthesia

11 Nothing in this study has suggested that postoperative complications of any importance, either early or remote, are any more frequent following spinal anesthesia than following any form of inhalation anesthesia We agree with Pemberton,² who said "I have never seen a serious complication as the result of the administration of spinal anesthesia as used in the Mayo Clinic"

12 No anesthetic is without certain inherent dangers, but merely because spinal anesthesia is a new anesthetic method, one should not be too appalled when an unexpected and untoward result occurs following its employment and be too unreasonable in condemnation of the method, at least until a careful review is made of the results obtained with ether, the occasional, yet inevitable, complications associated with which have, through long familiarity, been too largely disregarded

ABSTRACT OF DISCUSSION

DR JOHN S LUNDY, Rochester, Minn It does not seem to me that these results can be entirely related to the anesthetic agent or to the method of its administration The authors have stated that many of these patients were moribund when they were brought to the operating room In that case I doubt whether I would have chosen either the drop method or spinal anesthesia I do not know just what the arrangement of the authors is for supervision of the department of anesthesia, but I find that, if anesthesia by ether is to be satisfactory in a large group of cases, it will be necessary to provide an artificial airway for some patients Magill's large-bore smooth, soft rubber intratracheal catheter is very useful In a few cases it will be necessary to aspirate material from the trachea before the patient leaves the operating room If all the facilities are not available for caring for the occasional patient who does not take well an anesthetic such as ether, the morbidity rate will be increased over that of the group of patients who have available to them all the facilities for making anesthesia smooth If the morbidity is increased the probability is that mortality will be increased, for the group in which there is morbidity includes all who die, and there is a rather high percentage of deaths in cases in which grave postoperative complications develop Therefore it will be necessary to provide means for avoiding postoperative complications in order to reduce the mortality rate The paper is an eloquent plea for the use of modern methods and agents in anesthesia I believe that spinal anesthesia, ether anesthesia, or any other anesthetic agent or method should not be used as a routine Anesthetists now have a large choice of agents and methods The patient should have that agent and method carefully selected so that as many as possible of the postoperative complications may be avoided which will probably develop if a routine method has been adopted

DR GEORGE W CRILE, Cleveland The authors have presented an admirable analysis of the problem of anesthesia and have made clear that accurate data and sound thinking are required to reach safe conclusions I recall a front line hospital in France in 1917 where in the same operating theater, ether anesthesia, nitrous oxide anesthesia and spinal anesthesia were used The contrasts in the mortality from amputations of the thigh performed with these different anesthesia methods

14 Spielmeier H Veränderungen des Nervensystems nach Stovainanästhesie München med Wchnchr 55 1629 1634 (Aug 4) 1908
15 Davis Loyal Haven Hale Givens J H and Emmett John Effects of Spinal Anesthetics on the Spinal Cord and Its Membranes An Experimental Study J A M A 90 1781 1783 (Dec 12) 1931

were clear cut and striking. Of a hundred soldiers subjected to amputation of the thigh, performed under ether anesthesia, sixty-six died and thirty-four lived. Under spinal anesthesia, approximately twenty died and eighty lived. Under nitrous oxide, approximately twenty died and eighty lived. Dr. T. E. Jones of the Cleveland Clinic, in his personal experience in ninety-eight cases of one-stage abdominoperineal resections for cancer, reports that under spinal anesthesia the mortality rate was 12 per cent, in contrast to more than twice that mortality rate under ether anesthesia. Miss Hodgins and her group at Lakeside Hospital and Miss Adams and her group at the Cleveland Clinic Hospital have administered 112,000 gas-oxygen anesthetics to white patients with only three anesthetic deaths, or a mortality rate of 1 to 37,000. This series includes straight nitrous oxide anesthesia, nitrous oxide with local and regional anesthesia, and nitrous oxide and ether combined. Such a series presupposes a high order of training on the part of the anesthetists. In this series all the anesthetics were administered by highly trained nurse anesthetists. A small, separate series of Negro patients, however, shows four deaths, the obvious conclusion being that only the most experienced and the most skilled anesthetists should administer nitrous oxide to a Negro patient. The principle is established that nerve blocking involves every type of block anesthesia from mere local anesthesia to spinal anesthesia, as the only complete protection against shock. Gas-oxygen anesthesia, for a still unknown chemical reason, is equally a protection against shock. In many abdominal operations, gas-oxygen anesthesia fails to give the necessary relaxation, therefore, ethylene ether or spinal anesthesia is used. Spinal anesthesia carrying the highest anesthetic mortality should not be used in trivial or minor operations or in operations that have no shock mortality. On the other hand, as a rule, inhalation anesthesia should not be used in the major shock-producing operations. When shock per se is the paramount risk, spinal anesthesia should be used, when the anesthesia per se is the remaining risk, spinal anesthesia should be avoided.

THE PRESENT STATUS OF ETHYLENE

ISABELLA C. HERB, M.D.

HUBBARD WOODS, ILL.

March 12, 1933,¹ marked the tenth anniversary of the introduction of ethylene in the anesthetic field, and it seems a fitting time to discuss its merits, demerits, and general application in surgery.

In order to determine the present status of this agent, a questionnaire was sent to the leading anesthetists of the United States, Canada and foreign countries. The questionnaires were sent to anesthetists rather than to surgeons because it was thought that the attitude of the surgeon would be reflected in the answers of the anesthetists, as well as their own opinion. This supposition proved to be correct. An opinion based on this survey seems justifiable. One thousand questionnaires were sent out. A few were returned because of deaths or improper addresses. Five hundred and thirty-four replies were received. Two hundred and twenty were using ethylene and 314 were not using it. Ethylene was administered alone 737,815 times and combined with ether for varying periods 267,560 times, making the total of recorded ethylene anesthesia 1,005,375. Many anesthetists who were unable to give the number of ethylene anesthetics they had administered, because records were not kept, stated that several thousand, or from 70 to 80 per cent of all anesthetics, were with ethylene.

There were no explosions or deaths recorded by this group.

The various odors of ethylene are due to impurities and the administration of such ethylene may be accompanied by nausea, gagging, vomiting and more or less cyanosis. Impure ethylene usually produces an accumulation of yellow oily material in the machine connections. Since these objectionable features have been nearly eliminated by the reliable expert manufacturers, it is a rare occasion to have a patient refer to or object to the odor.

Ethylene is not unpleasant to inhale if it is administered slowly, with a liberal amount of oxygen during induction of the anesthesia.

The administration of nitrous oxide before ethylene is not practiced in the Presbyterian Hospital of Chicago because, as stated before, pure ethylene is not unpleasant if properly given and because of the feeling that a combination of the two gases on the same machine and in a patient's lungs may not be safe. So strong is this belief that we have separate gas machines for ethylene and for nitrous oxide, in other words, tanks of the two gases are never on the same carriage. The decision is made before operating as to which gas is to be used, and then its administration is continued throughout the operation unless a change to ether becomes desirable.

After an extensive experience with local analgesia, chloroform ether and nitrous oxide-oxygen, I feel that ethylene possesses distinct advantages over all other anesthetics, especially when combined with local infiltration in pelvic and upper abdominal operations.

One of the many advantages of any gas anesthesia is the early awakening with little or no vomiting and the ability to clear the throat of mucus, and the trachea and bronchi of aspirated stomach contents, pus from lung abscess or material following jaw, mouth and throat operations. Gas is not irritating to lung epithelium and consequently can be given when anesthesia becomes necessary following pneumonia or any acute respiratory infection. At present the two gases, nitrous oxide and ethylene, are available and quite naturally a decision must be arrived at as to their relative safety and efficiency if the advantages of each are to be taken into account. When ether is combined with nitrous oxide-oxygen, the explosive hazard is fully as great as it is with ethylene-oxygen. Further, ethylene has the advantage over nitrous oxide in that it produces greater relaxation, and better oxygenation can be maintained throughout long and difficult operations.

Cyanosis is distressing to both surgeon and anesthetist, especially when they are accustomed to the appearance of normal oxygenated blood.

The immediate safety of a gas anesthesia is due to the percentage of oxygen that can be administered with it. This consideration is an important one, as abundant research has shown. It is now quite generally agreed that blood changes depend on the amount of oxygen in the circulating blood, and as cyanosis does not develop in a properly administered ethylene anesthesia, it is quite clear that blood changes are practically absent. The results of the early studies of Luckhardt and his co-workers, relative to blood changes under ethylene anesthesia, have been repeatedly confirmed by other investigators. Brunbaugh² found "no changes in hemoglobin, no appreciable change in the icterus index, blood sugar is increased but quickly returns to the pre-anesthetic level. There was no increase in blood urea

Read before the Section on Miscellaneous Topics, Sessions on Anesthesia at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 15, 1933.

immediately following ethylene anesthesia and but a slight increase in twenty-four hours. A moderate temporary decrease of the carbon dioxide combining power of the blood. No change in coagulation time. No change in the character of the clot." Trout,³ from his researches, concluded that "ethylene-oxygen produces less alteration of the percentages of blood sugar, the coagulation time or the bleeding time than any other of the commonly employed anesthetics."

Ether is the only general anesthetic agent known at the present time that will produce complete relaxation in all types of surgical conditions. However, its use has been greatly reduced since the advent of ethylene. In abdominal operations, in which complete relaxation is required, a combination of ethylene and ether may be given which usually produces the desired relaxation. This failing all ether may be resorted to and continued till the peritoneum has been sutured, when a return to ethylene for the remainder of the closure may be practiced, thus considerably shortening the ether anesthesia.

Active intestinal peristalsis may occasionally interfere with the operative technic and the administration of ether becomes desirable, as ethylene does not stop peristalsis.

Operations requiring vapor anesthesia, and abdominal operations, are practically the only ones in which straight ether is administered in the Presbyterian Hospital. The number of abdominal operations in which straight ether has been given has been greatly reduced since the introduction of local anesthesia in combination with ethylene-oxygen. The best results with local anesthesia have been obtained by nerve blocking. The entire abdominal wall and peritoneum may be rendered anesthetic by a simplified bilateral blocking of the intercostal and lumbar nerves. When the nerve blocking has not been complete, peritoneal infiltration after the abdomen is opened will greatly aid the anesthesia.

When a deeper anesthesia is required than can be safely obtained by local anesthesia and ethylene, ether may be combined with the ethylene for short periods of time, either during the early stages of the operation or sometime during the anesthesia. This small amount of ether, apparently, does not affect the awakening period and has no ether after-effect.

The most common reason given in answers to the questionnaire for not using ethylene was the fear of explosion. This fear was held by the surgeon, the anesthetist or the hospital superintendent. Doubtless, the wide publicity given the early mishaps is responsible for this widespread fear. In some instances, particularly in the Far West, fire insurance rates were so increased that the use of ethylene had to be abandoned.

The most enthusiastic users of ethylene were those who reported many thousand anesthetics, conversely, those who were most positive that it had no advantage over nitrous oxide had had little or no experience with its use. There is almost a unanimous feeling among dentists that nitrous oxide is preferable to ethylene in their office work, because of the fear of explosions, because nitrous oxide oxygen is pleasant to inhale, because relaxation is not necessary and because the anesthetics are of short duration. Oral surgeons who use ethylene praised it especially for jaw operations and impacted teeth.

Two of the reasons given by several correspondents were the Cleveland disaster⁴ and "the Evansville explosion." As a matter of fact neither of these most

unfortunate happenings was due to ethylene. The Cleveland explosion was due to fire in the storage plant of X-ray films in a building apart from the operating department. The Evansville explosion occurred during the repair or manipulation of a tank of nitrous oxide, which it was thought might possibly have contained some ethylene from a backflow during an operation. The latter is a supposition without any proof and shows the prejudice toward ethylene or a general lack of knowledge that nitrous oxide-oxygen-ether is explosive. The greater number of explosions with nitrous oxide-oxygen-ether during or after anesthesia when the machine was idle, as recorded in answers to the questionnaire, shows definitely the explosiveness of this mixture. After a careful study made in the Evansville case, I have concluded that static electricity played a very important part in this sad fatal explosion.

The undue publicity given the explosive hazard of ethylene was unfortunate, because it has deprived patients, surgeons and anesthetists of a most valuable anesthetic agent. The answers to my questionnaire regarding nitrous oxide-oxygen-ether explosions were quite unexpected, because of the much greater number than had occurred with ethylene over the same period of time. It is regrettable that I did not include the number of nitrous oxide-oxygen-ether anesthetics in the questionnaire, because that would have given an opportunity for comparison.

The number of ethylene and nitrous oxide-oxygen-ether fatalities has not been large, considering the hundreds of thousands of anesthetics. However, a great deal may be done to diminish the hazard further. Many who are using ethylene and nitrous oxide-oxygen-ether are living in a sense of false security because of the inefficiency of their methods for static control or the lack of knowledge of the explosive nature of nitrous oxide-oxygen-ether.

An exhaustive study was made by Cheney and Folkman⁴ to determine the concentration of ethylene in the air of the operating room. Their observations are instructive and of practical value. Using a device developed by the Union Carbide Company for the detection of methane and other inflammable gases in coal mines, they were able to determine the actual percentages of ethylene in the air at any particular point desired during the course of the anesthesia. The instrument determines percentages of a combustible gas, up to and including the lower limit of inflammability. In the case of ethylene, the lower limit of inflammability is 3.02 per cent, that of ether is 1.71 per cent with air. At a distance of 10 feet or more from the patient's head, the concentration of ethylene was so small as to be indeterminable and after numerous tests in the area 6 feet or more from the head of the table the readings were confined to the territory within that radius.

GENERAL SUMMARY

1 No evidence of accumulation of building up of ethylene percentages in any portion of the operating rooms was shown after the longest period of anesthesia.

2 Electric switches (or similar apparatus) on the walls of the operating rooms were shown to be entirely harmless, as the maximum ethylene concentration at these points showed less than 0.1 per cent. It should be kept in mind that the minimum percentage of ethylene in air that is inflammable is 3.02 per cent.

³ Trout, H. H. Blood Changes Under Ethylene Anesth. & Analg. 9 (Sept-Oct) 1929.

⁴ Cheney, M. B. and Folkman, M. L. Anesth. & Analg. 9: 11 (Jan-Feb) 1930.

3 The tests demonstrate the very rapid "rate of diffusion" of ethylene in air, which, obviously, is the basic reason for the low concentration found

4 The tests showed that the only points when explosive mixtures of ethylene and air occurred were in the immediate vicinity of the face mask. The "dangerous area" may be described as one foot above the mask and two feet to the side of the exhalation valve. All the tests were made in hospitals of modern construction with no unusual ventilating systems

CONCLUSIONS

The danger zone so far as flammable mixtures of ethylene and air are concerned is confined to an area within a few feet of the exhaling valve of the face mask. Furthermore, the direction in which the exhalation of the patient is pointed, in case the face mask is equipped with an adjustable vent, is an important factor

INFLAMMATION OF ETHYLENE-OXYGEN

Tests were made by the Bureau of Mines to determine the limits of inflammability of ethylene-oxygen mixture. It was found that the ethylene content must be 80 per cent or higher, or, in turn, the oxygen content must be higher than 20 per cent. Nine volumes or more of carbon dioxide per volume of ethylene was found necessary to render ethylene noninflammable, and in a similar way it required 13.3 volumes or more of nitrogen per volume of ethylene. In view of the large amount of either of these gases required it is not feasible to use this method in practice as has been suggested, because the oxygen content would be so reduced that the patient's life would be in jeopardy

METHODS OF INSURING SAFETY

Safety in the use of ethylene-oxygen and nitrous oxide-oxygen-ether mixtures must be accomplished by removing sources of ignition such as open flames, gas burners, stove fires, alcohol lamps, lighted candles, the striking of matches, cauteries near the point of administration, smoking near the gas machine, fulgurating machines with an open spark gap, and x-ray rooms

That there is any advantage in passing ethylene over or through water to prevent explosions is open to question. In order to prevent freezing of the valves, the compressed gas is made very dry and will not be saturated by passing through water unless the water is kept warm or the gas is broken into very small bubbles

From my own experience and the experience of other anesthetists, the conclusion has been reached that it is the static from without and not from within the machine that is to be feared. Several of the reported explosions occurred sometime after the close of the operation, when the machine had been "idle" for from a few minutes to two or more hours. The explanation of such accidents is simple. The machine had accumulated static on its external surface in sufficient amount to cause a spark when contact was made. If the charge on the machine is discharged through grounding, such accidents will not occur. During cold dry weather the air is full of static electricity and any moving body accumulates a sufficient amount to produce a spark, as is evidenced by a shock when one touches an electric light button or lights a gas jet after scuffing along on a rug. It is a mistake to believe that the flow of gas creates static, although the explosion may occur at the point of exit of the gas because of a spark at that point. Two of the explosions (one ethylene and one nitrous oxide-oxygen-ether) in our hospital were caused by

friction, one on the outside of the breathing tube and the other on the outside of the bag some distance from where the gas was being delivered to the patient

A relative humidity of 60 per cent will render surfaces conductive and prevent an accumulation of static. Doubtless, certain climates are so humid that static electricity is discharged and there is little or no danger of an explosion from this source, consequently, no precautions need be taken. If the humidity could be kept high enough in the operating rooms, it might be difficult to develop electrostatic charges, and any charge brought in from the outside would leak off. The drawbacks to a high humidity plan are, first, that the humidifying system would need constant watching and a drop in humidity might pass unnoticed and prove disastrous, second, that a high humidity, at the temperature maintained in the operating room, would render working conditions very uncomfortable. In considering the prevention of explosions, it was felt that a system was desirable which would not require constant supervision, and which, at the same time, would cause no discomfort to those concerned

Our plan of preventing electrostatic explosions was that of having all objects on which a charge might exist connected together by a metallic connection and held at a standard potential, such as ground

Because of the fact that charges might be brought in from outside, as well as developed by walking across the floor of the operating room, the conclusion was reached that a positive grounding system was needed, a system that would always give a dependable ground, that would ground any person or apparatus brought up to the operating table or gas machine, and that would not require constant watchful supervision

It was decided that the best plan at the time would be the installation of a sheet of steel on the floor, large enough to accommodate surgeons, anesthetists, nurses, the operating table and the gas machine. The sheet was installed and is of such a size that any person approaching the gas machine or operating table will first be grounded by stepping on the outer margin of the metal plate. Later, the following floor plan was devised and was installed. The floors and base are what is commonly known as cloisonne terrazzo, similar to the kind of floors used in some of the large rooms in modern hotels. Briefly, it consists of small squares of terrazzo, separated by narrow brass strips. For our purposes these strips are placed 5 inches on centers each way and are slotted together at the intersections. After the terrazzo material hardened, the entire surface was ground down to a smooth finish, which brings the edges of the strips flush with the floor. The general appearance is that of a tile floor, except that the joints are brass instead of cement. This grille of brass strips is electrically connected together and then grounded to the water pipes. Each piece of movable equipment, such as tables, stands and anesthetizing machines, is equipped on the under side with several small link brass chains, which are long enough to drag on the floor for several inches

Regardless of the position of the equipment on the floor, at least one of these chains is in contact with a brass strip, thus all are grounded and a difference in potential is impossible. The smallness of the squares of terrazzo also grounds the operators and assistants, as they move about in their regular routine of work, which eliminates the possibility of an assistant going to another room or ungrounded equipment and bringing back a charge of differential potential

The points of the system that was devised to prevent static may be thus summarized

1 The terrazzo-brass floor that has been described or a grounded metal plate of nonrusting furniture steel, large enough to accommodate the operating table, the staff and the gas machine, with an unused margin on all sides, has been installed in the operating rooms

2 The netting covering the breathing tube and bags is made of tinsel cord, which is connected to the metal frame of the machine

3 Pendent brass chains, two or more in each case, are fastened to the axles of the operating table and the gas machine to ground them to the metal floor or the terrazzo floor

4 A chain is used with a small metal plate on one end, which is placed under the patient to ground him to the table. The other end is thrown over the shield at the patient's head and down to the grounded table

Experiments, and the administration of more than 20,000 anesthetics (since its installation) without the slightest indication of an explosion, confirm the belief that this system of grounding and of electrical interconnection will prevent electrostatic sparks

While it may seem that the matter of connections has been entered into with considerable detail and that fine points have been followed to the extreme, it was felt that, to be on the side of absolute prevention and protection, a conclusion should be reached on every point that could possibly be foreseen

Electric fans of the alternating current type have no brushes, consequently there is no sparking unless the fan is out of order. Such fans may be used in the operating rooms with safety. If operating rooms are small and the point of administration is within a few feet of the electric light switch, it is good protection to have mercury switches, which do not produce a spark when turned on and off, or have the switches outside the operating room

In passing, I may state that those who have questioned our method for the control of static electricity are not familiar with its completeness, its simplicity, and the small expense connected with its installation. That it is efficient there can be no doubt, when one considers the many thousand anesthetics that we have given since the grounding was put in, without the slightest indication of an explosion, although the administrations were under exactly the same conditions that obtained during the first few hundred anesthetics (administered before grounding), when several explosions occurred with both ethylene and nitrous oxide-ether

The question as to the cost of ethylene must be a relative one, because the administrator, character of the operation, the amount of rebreathing practiced, and the type of gas machine all play their part in the amount used. All things being about equal and taking the record of four anesthetists in a like number of different hospitals, and averaging them, we found the cost to be about \$1.60 an hour. The original cost of ethylene quite naturally must vary. Hospitals using a large amount would be able to purchase it more cheaply than those using a small amount

It has been said that ether explosions and fires would number at least a hundred a year. Is it because they are so common that little publicity is given them?

The deaths from explosions during oxygen-ether anesthesia lead to the belief that the mixture of pure oxygen and ether form a more highly combustible

agent than does ether and atmospheric air. It is not generally known that a gallon of ether, under proper air conditions, has the explosive power of 75 pounds of dynamite. While the questionnaire did not include ether accidents, many volunteered such information

Because of the general knowledge of the fire hazard of ether, certain precautions are generally observed. When an accident occurs, it is due to carelessness or caused by a badly constructed vaporizing machine. No one would think of discarding ether because of the possible accidents it might be responsible for. Then why abandon such a valuable agent as ethylene when its hazards can as surely be controlled?

Summing up the reported explosions, injuries and deaths, I find the following

Ethylene, twenty explosions, with one injury and five deaths

Mixture of nitrous oxide-oxygen and ethylene, two deaths

Nitrous oxide-oxygen-ether, thirty-nine explosions with seven injuries and five deaths

Nine explosions occurred when the machines had been idle from a few minutes to two or more hours. The machines had been used for ethylene administration in two instances and for nitrous oxide-oxygen-ether in seven of these explosions

From the foregoing it is evident that nitrous oxide-oxygen-ether forms as highly an explosive mixture as does ethylene, and precautions against this danger are fully as urgent as is required with ethylene-oxygen

Some of the injuries that occurred both with ethylene and with nitrous oxide-oxygen-ether were due to the ignition of the ether in the glass ether chamber of the gas apparatus. The breaking of this chamber scattered the glass and ether about the room, causing fires and burns

Two deaths were recorded due to impure ethylene (carbon monoxide), two in the hands of "inexperienced administrators," and one due to "vasodilatation"

It appears to me that the last named death should be charged to operative conditions, such as hemorrhage, as ethylene does not produce or contribute to shock. If it destroys life, it does so through insufficient administration of oxygen, which would be asphyxia

ABSTRACT OF DISCUSSION

DR ARTHUR DEAN BEVAN, Chicago. In the subject of anesthesia, a joint laboratory and clinical research is the most scientific method of study. Ethylene was introduced in the surgical clinic of the Presbyterian Hospital in 1923. We used it about 2,500 times and during that period had a number of explosions. Fortunately, nobody was hurt. The rubber tubing at the mask was blown out, but it so disconcerted us that we gave it up. I ordered ethylene out of the hospital until the whole situation had been carefully analyzed. We found that the explosions were due to the static spark and that to eliminate the static spark it was necessary to ground the entire operating group. That could be done by placing the entire operating team and plant on a steel mat wired to the plumbing. This is described in my article on anesthesia in *THE JOURNAL*, Nov. 21, 1931, page 1530. We began the use of ethylene again and have used it in 27,000 cases without an anesthetic death and without an explosion. Ethylene has a wide place in modern anesthesia. I think Dr. Luckhardt and Dr. Herb have made the greatest contribution to anesthesia that has been made in the last twenty years. From my experience in clinical research on anesthesia, I think a most unfortunate situation has arisen in this country, especially in the hands of men of limited experience and men who lack judicial minds. Too many dangerous agents are being used. Among the most dangerous I would name first spinal anesthesia. There is no doubt that

spinal anesthesia has a higher mortality than chloroform. I think the time has come when either spinal anesthesia should be eliminated or its use should be restricted to a very narrow field. There are several other methods of anesthesia that should be used with the greatest possible caution. I refer to intravenous anesthesia and to intrarectal anesthesia. These methods are beyond one's control, once they are administered. The safest, the simplest and the most easily controlled methods of anesthesia must be selected. Today the entire field of anesthesia can be covered in the safest and most satisfactory way with the use of three agents: local—including blocking—ethylene and ether. If preanesthetic agents are employed, the safest is the combination of morphine and atropine in moderate doses.

FOUR FATAL CASES OF UNSUSPECTED AMEBIASIS

PRELIMINARY REPORT ON ONE ASPECT OF THE
RECENT CHICAGO EPIDEMIC

CHARLES C. LUND, MD
AND
THOMAS R. INGHAM, BS
BOSTON

Following a meeting of about 125 members of the lumber trade who were drawing up a preliminary draft of a code for their industry, there occurred numerous cases of acute colitis and at least five deaths. The meeting was held in Chicago from June 30 to July 2, 1933. In all cases the symptoms began after the meeting was over and when the men were scattered all over the United States and Canada. We became interested in the situation not because of experience with these or other cases of amebic dysentery but because of close friendship and relationship, respectively, to two of the men who died.

The investigation of this situation is far from complete, owing to difficulties in securing rapidly information from many widely scattered localities. This preliminary report is made, however, because it has been found that these cases are a part of a much larger epidemic and because the diagnosis was not sufficiently suspected when the cases turned up sporadically at widely separated points. This criticism is made in all due humility and applies to the present authors themselves, who have no illusions that they would have handled the cases any better than they were handled. In fact, the senior author was consulted by the physician and family of patient 1, and never once (during the life of the patient), thought seriously of amebiasis as the diagnosis, having been trained to think of amebiasis only as a disease found for the most part in the tropics. In view of the fact that *THE JOURNAL* has contained several excellent articles on amebiasis by Craig¹ and others in the last two years, this shows how difficult it is to teach subjects that are not commonly seen and appreciated.

The epidemic (which was mentioned in the newspapers of the country, November 10) has been placed under control by the department of health of Chicago under the leadership of Dr. Herman N. Bundesen. A preliminary report on the epidemiologic aspects of the situation was presented by Tonney, Hoeft and Spector² before the American Public Health Association

at its meeting, October 9. At the time of this report, Tonney and his co-workers were not aware of the cases presented here. The source was a group of carriers working in the kitchen of a Chicago hotel. The five fatalities among members of the lumber trade all occurred in guests at this hotel.

REPORT OF CASES

CASE 1—History—W. B., a man, aged 43, president of a Boston lumber company, had always been well save for occasional attacks of abdominal pain, attributed by him to mild appendicitis. He had been on a Mediterranean cruise in February, 1933. July 12, the patient suffered an acute attack of epigastric pain with immediate nausea followed by vomiting twelve hours later. He was then admitted to a hospital in New York. There was suprapubic tenderness, and pain on the right side by rectum, but no spasm or tenderness by direct palpation over McBurney's point, there was absence of diarrhea or bloody stools. The white blood count was 18,000 with 90 per cent polymorphonuclears. The temperature was 99.6 F. The urine was normal.

July 13, laparotomy was performed with a preoperative diagnosis of appendicitis. A slightly inflamed appendix and ulcer of the cecum were found, the appendix and cecal ulcer were removed and the wound was closed without drainage.

The pathologic examination revealed that the appendix measured 6 by 5 cm. The serosa was pink and rather granular, and there was a diffuse vessel injection. The lumen had been opened at the proximal two thirds. Cross-section of the distal third showed the lumen apparently obliterated by fibrous tissue. The mucous membrane of the medial two thirds was rough and covered with bloody fluid. Sections were taken from each area. There was also a circular piece of tissue, 4 cm in diameter, with a wall 0.7 cm thick and a concavity of one surface. The outer surface was thick around the periphery but with a center which was gray with some necrotic material. The inner surface was somewhat corrugated and was gray around the periphery and red in the center, but there was friable necrotic tissue in the center.

Microscopic examination disclosed many scattered leukocytes in the wall of the appendix. There was no abscess formation nor necrosis. The wall of the cecum showed a large zone of ulceration with hemorrhage and masses of polymorphonuclears. There was intense engorgement of the vessels, some of which showed fibrin and leukocytes in the lumen. Many phagocytes were seen with red cell inclusions.

The pathologic diagnosis was acute gangrenous ulceration of the cecal wall, acute appendicitis.

The next day the patient began to have for the first time severe diarrhea, which gradually became very much worse. Believing that an abscess had developed, surgeons again explored the right lower quadrant five days later and found an almost gangrenous cecum and inflamed ascending colon. The wound was closed after insertion of a soft rubber wick. Two days later a fecal fistula developed, followed in ten days by generalized peritonitis. The patient died, August 4.

Many examinations of stools were made from July 19 to July 26 for typhoid bacilli and *Endamoeba histolytica*. These were negative. Blood agglutination tests for typhoid and bacillary dysentery were also negative.

Autopsy—The entire large bowel was ulcerated, the cecum and ascending colon were gangrenous and there appeared to be only a small zone near the rectal end which still preserved a little mucosa. The liver showed no lesions and observations otherwise were not remarkable. Microscopic examination of the ulcers of the bowel revealed *Endamoeba histolytica*.

CASE 2—History—A. M., a man, aged 64, president of a Toronto lumber company whose past history was unimportant, had been in Japan in 1929 but had not been ill during or after this trip. About July 28 he began to feel tired and feverish and to have a headache. There were no abdominal symptoms at all. The temperature was 102 and the white count 8,000. This condition continued for two weeks, when he began to have diarrhea of from three to four movements a day. Three days later (August 14) he had a sudden severe pain in the abdomen and right shoulder. On examination he presented the

¹ Craig, C. F. The Amebiasis Problem. *J. A. M. A.* 98: 1615-1620 (May 7) 1932. The Symptomatology of Infection with *Endamoeba histolytica* in Carriers. *ibid.* 88: 19 (Jan. 1) 1927.

² Tonney, F. O., Hoeft, G. L., and Spector, Bertha Kaplan. The Threat of Amebiasis in the Food Handler. *J. A. M. A.* 101: 1638 (Nov. 18) 1933.

appearance of shock, with marked spasm of the entire abdomen and tenderness in the right lower quadrant. Two days after this attack he was moved to a Toronto hospital, the tenderness in the right lower quadrant persisting. A barium enema showed moth-eaten irregularities of the cecum and ascending colon. The white count was 25,000. August 19, an abscess in the right lower quadrant was drained. August 24 a right subphrenic abscess was drained. The patient died, August 26.

Autopsy—The abdomen showed much necrotic intestine and advanced generalized peritonitis. The large intestine was too gangrenous from the cecum to the transverse colon to show definite mucosal lesions, distal to the hepatic flexure the bowel showed multiple acute ulcers, with "slightly raised margins formed of swollen mucosa" and dark brown, "shreddy" necrotic centers. The appendix was distended at its distal portion. The small intestine had several areas of superficial ulceration, apparently related to a preceding adjacent and severe peritonitis. The liver weighed 2,150 Gm and showed in the right lobe a large abscess, honeycombed and ragged in appearance. Microscopic examination of rectal ulcers and the appendix showed invasion by *Endamoeba histolytica*, with accompanying cellular infiltration. The liver sections merely showed chronic suppurative inflammation without specific characteristics.

CASE 3—History—M. E. R., a man, aged 67, president of a Seattle lumber company, gave a vague history of occasional attacks of diarrhea for the past three years. Acute diarrhea began, July 15. Three days later proctoscopy showed ulcers of the upper part of the rectum. He went against advice from Seattle to Washington, D. C., and on his return, August 1, the diarrhea was worse. Proctoscopy was again performed and he was sent to a hospital in Seattle. At first, physical examination was essentially negative, except for the obvious appearance of exhaustion. The temperature was 102. Repeated stool examinations showed no amebas. A barium sulphate enema, August 2, showed that the colon filled rapidly and apparently normally with the exception of a contracted rectal pouch. The white blood count was then 14,000. During the first three weeks the patient had chills and fever, continued diarrhea, and increasing prostration. Instillation of 1,500 silver nitrate by rectum was given without improvement. Repeated search for amebas in the stools failed to reveal them. August 21, pain and localized tenderness developed in the right lower quadrant of the abdomen. August 28 exploratory laparotomy and appendectomy were performed. Free fluid was found in the abdomen, a smooth mass was found in the rectosigmoid colon, and the cecum was large and edematous. The appendix was inflamed. "This seemed to be more of a continuation of the same process that was in the cecum." The patient stood the operation well at first but then gradually failed and died, September 5.

Autopsy—The abdomen showed a recent unhealed right rectus incision with considerable necrosis and sloughing of muscle and fascia. The large intestine was enormously distended with masses at the cecum, transverse colon and rectum. These were the sites of large ulcerations covered with thick gray, necrotic membranes and surrounded by edematous fibrous and fatty tissues. The small intestine showed no evidence of ulceration. The liver contained in the right lobe an "encapsulated cavity filled with thick, dirty grayish material." Microscopic examination showed ulcerated areas containing many amebas and cysts containing four nuclei. Purulent material from the hepatic cyst showed nonmotile *Endamoeba histolytica*.

CASE 4—History—A. C. L., Jr., sales manager of a lumber company in Louisiana whose past history was unknown, had an attack of "indigestion" July 14 but went to Washington, D. C., from Louisiana the next day. The day after his arrival (July 18) he began to have diarrhea and indigestion but attended to business. July 20 he started home suffering from intense diarrhea all the way and arriving July 22, very much dehydrated. He was taken at once to a hospital. The stools were examined for amebas but were negative. He showed a positive Flexner agglutination and was given large doses of dysentery serum. He continued to grow worse and showed signs of peritonitis about July 28. Two days later, amebas were found in material from the ulcers removed by proctoscopy. The patient died, August 2 of peritonitis in spite of active treatment started the day before.

Autopsy—We have only fragmentary data and do not know whether autopsy was performed.

CASE 5—R. L. K., executive of a lumber company in Louisiana, died from acute colitis, according to a letter from his brother, three weeks after the Chicago meeting. His physician has not sent any report as yet, and therefore it is not certain that he had amebic dysentery.

DIAGNOSIS

In the northern part of the United States, acute ulcerative colitis is probably more commonly due to a streptococcus or other similar organism than to amebas. Cases 1, 2 and 3 were all considered to be instances of such nonspecific colitis. There is apparently no way in which the two types of colitis can be told apart on clinical grounds alone.

Partial reference to recent literature shows that the symptoms and early course of amebic infections may be very variable. That is certainly true of the five cases reported here. Any abdominal condition may be simulated, and diarrhea sometimes never occurs in the whole course of the disease.³ Surgeons who work in tropical countries have found that they must be constantly on their guard to avoid operation in cases of amebiasis under the diagnosis of acute appendicitis.⁴ This is also seen well in an article on the occurrence of amebiasis in Spain.⁵

However, the one important fact shown by the cases in the present series is not that the symptoms are variable but that repeated negative examinations of the stools or of material from the ulcers removed by proctoscopy cannot be trusted to rule out amebiasis.

TREATMENT

Although each of these patients was of such standing in his community that he secured the services of some of the leaders in the profession, not one received treatment that can be considered adequate. There is no question that emetine is practically a specific for the acute attack when given before intestinal perforation has occurred, but none of these men were given it at all, except patient 4, who received it too late. After the diagnosis is suspected, not more than a few hours should be spent in laboratory or other investigations before specific treatment is started. Treatment must be given even if the tests are negative. The dose of emetine is 0.065 Gm once a day, intramuscularly. Chinofon or similar products are also useful and should be given at the same time as the emetine. The dose of chinofon is 0.5 Gm by mouth or 3 Gm in 200 cc of water to be retained by rectum. A good method is to give it by mouth and by enema on alternate days. A full discussion of the treatment of amebiasis may be found in an article by Willner.⁶ The treatment of amebiasis to the extent of completely sterilizing all lesions is often difficult and will not be considered here. Emetine must not be given for more than six to ten days, as it is toxic and may lead to myocardial failure. However, if the patient has amebiasis, he will be greatly improved and the danger of acute perforation will be averted in less than ten days. The chinofon also should be stopped for a while after ten days, although it is not as toxic as emetine.

FREQUENCY OF AMEBIASIS

Amebiasis is considered to be a rare disease in the northern part of the United States and in Canada. It is probably not nearly so rare as it is supposed to be.⁷ In 1932, only four cases and two deaths were reported in the whole of Massachusetts. Dr. Anderson feels that many diagnoses are made that are not reported and in addition that many more cases occur that do not have the correct diagnosis made. In view of the outbreak reported here, it is obvious that even if it has been a rare disease in the past it is a disease that must be given much more consideration in the future.

SUMMARY AND CONCLUSIONS

- 1 Four deaths occurred from amebic infection.
- 2 The infection was probably received from carriers, who were found to be working in the kitchens of a Chicago hotel.
- 3 Cases of suspected amebiasis must be given treatment by emetine or emetine together with chiniofon, irrespective of whether or not the diagnosis is confirmed by laboratory investigations.⁸

under conditions of a varied alimentary supply of soluble aluminum salts.

The study of the elimination and the retention of aluminum is of importance, first, because aluminum is almost universally present in foodstuffs, secondly, because the metal is used extensively for the manufacture of cooking utensils and food containers, and, thirdly, because the data on the distribution of aluminum after feeding aluminum salts are of value in the elucidation of the absorption, retention and elimination of other metals.

In addition to its natural occurrence, aluminum may enter foodstuffs by contact with the metal or by the addition of salts of aluminum. The extent to which aluminum enters foods cooked in aluminum utensils has been shown elsewhere² to be extremely small, being near the limits of detection. As was to be expected, acid foods and foods to which sodium bicarbonate had been added acquired more aluminum than did others. It was found also that more aluminum enters food from stained than from bright utensils, and that sugar retards this action.

The chemical properties of aluminum form a clear background for the study of its pharmacologic action. Aluminum hydroxide is amphoteric with an iso-electric point at about p_H 5.5. In the presence of the phosphate ion, an aluminum phosphate is formed, insoluble at about p_H 2.8 and lower acidities. The pure tertiary phosphate, $AlPO_4$, probably does not exist. Under the influence of water, various degrees of hydrolysis occur to give basic phosphates. Organic hydroxy acids tend to prevent the precipitation of aluminum as a phosphate. The formation and precipitation of aluminum phosphates in the alimentary tract are undoubtedly also influenced by foods and their digestion products.

The older literature on the fate of orally administered aluminum is confusing because of the employment of inadequate methods for determining aluminum in tissues. The newer published evidence, based on the application of more refined methods of analysis,³ is "that the concentrations of aluminum in biological matter must invariably be very low."^{2e}

EXPERIMENTAL

Selection of Animals—Guinea-pigs were chosen in these experiments because they present another and a markedly susceptible species in their response to alimentary aluminum. Guinea-pigs readily consume a porridge type of diet in which soluble aluminum salts most suitable for absorption may be incorporated. The dietary habit of these animals is most favorable to maximum absorption of aluminum, for when food is constantly available for consumption their stomach and intestines contain food continuously.

Constitution of the Experimental Diet—The diet chosen had the composition shown in table 1. Its average nitrogen content was found to be 0.49 per cent, phosphorus, 0.154 per cent, calcium, 0.116 per cent. Of the various ingredients, pumpkin was used especially for its flavor, milk powder for caloric value and vitamins, starch for facilitating the reconstitution of the dried pumpkin colloids that resist imbibition of water, and bran for roughage. The food was cooked in a pyrex flask arranged as a double boiler. The lost water was replaced and the desired aluminum solution containing aluminum in the form of lactate³ or of chloride, or a mixture of chemically equivalent proportions of these two salts was added to each respective batch type of food as required. Glass mixing and

Water or aluminum salt solution	100

feeding dishes were used and silver-plated spoons were used for stirring. Ten grams of spinach was fed daily as an antiscorbutic.

Effect of Aluminum Phosphate Formation—When half the phosphoric acid of an aqueous solution is combined with alkali, the solution is approximately neutral (pK secondary phosphoric acid = 7.16). If aluminum phosphate (approximately AlPO_4) is precipitated out of such a solution on the addition of aluminum chloride or lactate, the solution becomes more acid, for base is lost and the hydrochloric and lactic acids left in solution are stronger acids than secondary phosphoric acid. It is to be noted that this result is not due to hydrolysis of aluminum salts, which would give rise to an acid reaction, but that the acidification of a practically neutral food containing a phosphate must be explained in some other way. In our instance we have a food without dissolved aluminum, since it is eventually precipitated. Because it was conjectured that aluminum phosphate would be refractory to absorption in the intestine, it was deemed necessary to control the possible systemic effect of the increase of the acid in the diet. This fact accounts for our use of the three types of aluminum salt additions.

The addition of aluminum chloride to a diet that is neutral in reaction amounts to abstraction of an equivalent amount of phosphate, but the addition of only half an equivalent of hydrochloric acid

Aside from a tendency to phosphate starvation, there must be recognized in this instance the possibility for acidosis to occur. We were aware of this circumstance but proceeded nevertheless because we were interested in trying aluminum under any adverse circumstance whatever, especially since this chemical reaction also favors a greater acidity in the intestine than that of a neutral diet.

³ Aluminum lactate was made by dissolving aluminum chloride in water, adding lactic acid, distilling off the hydrochloric acid and water and allowing crystallization to occur. It could not be recrystallized from water, presumably because a basic lactate formed that was less soluble, although the aluminum content was approximately the same. We added a solution of the salts of aluminum to the animal diet to insure that the aluminum was dissolved at least at the start.

If aluminum is added as a mixture of stoichiometric amounts of aluminum lactate and aluminum chloride, the same reaction goes on, but lactic acid is liberated. The latter tends to increase the acidity of the intestine but does not tend to produce any acidotic condition in the system of the animal, as the acid is metabolized.

If aluminum is added as aluminum lactate, sodium lactate and lactic acid are formed. The acidity of the intestine probably remains practically the same as in the previously mentioned instance, but there is a distinct antacidotic effect in the system. The extra lactic acid introduces another factor, namely, that of aluminum phosphate remaining in pseudosolution or in solution, and to this extent it would therefore favor absorption.

The addition of aluminum lactate duplicates as closely as possible the condition occurring when aluminum is added to food by virtue of solution of the metal. Any method of adding salt would be satisfactory, however, if only a small amount of aluminum were added. But for the larger amounts we chose all methods so as to have the factors mentioned under control.

Care and Feeding of Animals—An amount of fresh food based on the average ad libitum consumption was offered daily, seven days a week. Any food unconsumed after twenty-four hours was removed and its weight deducted from the amount supplied. Tap water was given ad libitum by means of inverted bottles with pyrex tips. Bottles and cages were sterilized two or three times weekly. The guinea-pigs were housed separately in cages of knockdown construction, built of tinned iron wire screen and about 10 by 15 inches in area. The animals were elevated about 1 inch above the tray bottom, with a tinned wire screen through which feces could drop. The tin plating was replaced from time to time by redipping. Tin was used, because it had been shown by one of us⁴ that this metal is not absorbed from the intestine and because tin is resistant to corrosion by the alkaline cresol bath used for sterilization.

TABLE 2—Recovery of Aluminum Added to Beef Liver

	Before Ashing Mg	After Ashing Mg
Aluminum added	0.01	0.01
Aluminum present blank	0.125	0.125
Aluminum found	0.1755 0.1725	0.1725 0.1715
Net recovery	0.0535 0.0475	0.0475 0.0465

After a preliminary observation period for excluding diseased animals, the guinea-pigs were divided into groups and each placed on a diet containing added aluminum (calculated as the metal) from zero (controls) to 1.167 parts per million of consumed food. The latter figure represented seven eighths of the stoichiometric equivalent of the total dietary phosphorus and, incidentally, about the maximum aluminum that would be consumed by animals, owing to the taste imparted to the diet.

Four series of experiments were conducted, the first two of long and the last two of short duration. Series 1 and 2 were with animals obtained from the Kansas State Agricultural College, Manhattan, Kan., series 3 and 4, with animals from a local breeder-dealer.

⁴ Schwartz E. W. and Clarke W. F. Some Observations upon the Pharmacology of Tin. *J. Pharmacol. Proc.* 31: 224-225 (Jan.) 1931.

Analysis of Tissues—All animals were killed with ether. They were immediately dissected with steel instruments, and the tissues were washed with distilled water and stored in sealed glass containers in an electric refrigerator. The colorimetric chemical method used for the determination of aluminum is described elsewhere.¹⁵ The recovery of aluminum added to samples of 25 Gm of beef liver before and after ashing is shown in table 2.

The data in table 2 indicate that aluminum added to animal tissue can be recovered quantitatively within the experimental error of the method of analysis.

EXPERIMENTAL RESULTS

A summary of the chemical analyses of the aluminum feeding experiments will be found in tables 3 to 6. All analyses were done at random, except that those in tables 5 and 6 followed those in tables 3 and 4. For practical purposes the data may be divided into two groups, series 1 and 2 constituting a long-time feeding of added aluminum and series 3 and 4 a short-time feeding.

The analytic data reveal several outstanding characteristics, as follows:

There is more aluminum found in the case of the brain and spinal cord, the fewer the animals represented in the composite sample (series 1 and 2).

Both the liver and the heart groups of tissue within themselves may show only minor variations in aluminum content. Any difference between the experimental and the control animals as regards the soft tissues is relatively slight.

The highest content of aluminum in any group of tissues is found in the carcasses in series 3 and 4, composed of younger animals.

There is a considerable difference between the aluminum content in the carcasses of the controls of the first two series of experiments and the controls of the last two series.

The high content of aluminum when small samples were taken is probably due to the difficulties of analysis of small quantities of material. It was hoped that the grouping of the brains and spinal cords would provide a large enough sample for the accurate determination of the aluminum content. Experimental animals 17 and 68 provided only 112 Gm of tissue, or a total of 0.028 mg of aluminum. The aliquot used for analyses contained apparently only 0.0056 mg of aluminum, approximately the limit of accuracy of our method.

The aluminum present in the soft tissues of those guinea-pigs receiving added aluminum salts indicates that aluminum is absorbed to a slight extent. However, the absorption as indicated by deposition in the tissues is not proportional to the aluminum concentration in the diet, as evidenced by the fact that no differences appear between animals receiving 25 parts per million and 350 parts per million of the metal. At 700 parts per million additional metal may be deposited because of the diminished protective action of the constant phosphorus intake. At some level below 25 parts per million, absorption may become proportional to concentration or complete absorption may occur. Certainly the level for complete absorption must be very low, or a higher aluminum content would be noted in the tissues.

The noticeably higher aluminum content of carcasses is apparently due to a slight deposition of aluminum in the relatively inactive tissue, the bones. The animals of series 1 and 2 were adults at the end of the experi-

ment, those of series 3 and 4 were growing animals. The differences in the aluminum content of these two groups is probably due to the deposition of aluminum with calcium phosphate during growth and, later, its removal as bone development ceases. This difference, due to age, is apparent between both the experimental and the control animals. In fact, the old animals receiving added aluminum in series 1 and 2 had no more aluminum in their carcasses than the young controls of series 3 and 4. The controls of series 1 and 2 (old animals) contained so little aluminum that it could only be estimated as being below the lower limit of the method of analysis.

If cumulative effect is defined as a gradual increase of slowly eliminated material as a result of the absorption of repeated doses over a prolonged period, the result of which is to cause the delayed appearance of certain definite physiologic effects, then we have demonstrated that aluminum is not cumulative in its properties, as in the amounts absorbed there is no evidence whatever of a direct systemic action of aluminum. Its deposition reaches a maximum in soft tissues (less than one part per million in the guinea-pig) and is independent of the duration of feeding or of the concentration fed after the condition for maximum intestinal absorption has been reached. Furthermore, it has been shown that there is no direct relation between added dietary aluminum and the aluminum content of the carcass (bone), at least until such a time as the diet becomes inadequate in phosphate due to the addition of aluminum, and then only when the bone is actively growing.

It appears that the absorption of aluminum (and iron) from the digestive tract is governed by the dietary phosphorus, existing after digestion as phosphates. Aluminum lactate and aluminum chloride were added to the diet in amounts stoichiometrically equivalent (1,400 parts per million) to the total phosphorus. With these large doses, the two salts were of practically equal potency in producing a complete deprivation of blood phosphorus, leading to a fatal outcome in about four weeks. This grossly exaggerated condition of aluminum concentration with reference to phosphorus in the diet can never be encountered with the aluminum naturally present in the diet or derived from aluminum utensils.

The hydrochloric acid, which is liberated as a result of the precipitation of aluminum phosphate by addition of aluminum chloride, apparently did not place any burden on the animal or have any influence on the absorption and deposition of aluminum. So far as could be told, these animals were precisely similar to those receiving all their aluminum as aluminum lactate, in which case there was an equal tendency toward alkalosis.

Our data and conclusions differ in certain respects from those which have been reported recently in the literature, since we have undertaken primarily the study of the pharmacodynamics of aluminum. Our analyses justify the earlier conclusions of McCollum, Rask and Becker^{2a} that aluminum is not present in biologic material, since by our analytic method we can determine less aluminum than their method was capable of revealing. The aluminum concentrations in the

5 The tissues of these animals were analyzed by a method which was later shown to be unreliable and the data therefore are of no value. A preliminary report has been made¹⁶ on the effects of phosphorus starvation produced by the ration containing 1,400 parts per million of aluminum or an equivalent amount of iron. A complete report will be published later.

tissues of guinea-pigs that we have observed are lower than those reported by Myers and Mull⁶ for rats and for man, and, moreover, our individual analyses are subject to less variation for similar tissues analyzed in a uniform way. We differ from Underhill and Peterman⁷ in finding considerably less aluminum in guinea-pigs than they did in dogs. Our data are in very close agreement with those of Tourtelotte and Rask,⁸ who found by spectrographic analysis of various control rat tissues from 0.05 to 1 part per million and from 0.2 to 1 part per million after feeding 600 parts per million of aluminum for three months. They concluded that "aluminum present in the diet is not absorbed and deposited." Lewis^{2f} has ascertained by spectrographic technique that human blood is usually aluminum free but that small amounts, from 0.3 to 1.2 parts per million, may be found in the blood within forty-eight hours of a liberal feeding of aluminum salts. These studies are in general agreement with ours in demonstrating that the problem of aluminum deposition in tissue has now ceased to be one of major pharmacologic importance.

We do not place implicit confidence in variations between individual animals. There are few types of pharmacologic experiments in which one may not find variations with a maximum value of three or possibly even four times the minimum. This observation has made us cautious to accept any save the most apparent conclusions.

Considering the relatively small amount of aluminum that would get into the diet as a result of corrosion of aluminum metal in contact with food^{1g} in comparison with the large daily intake of phosphorus, there appears to be no possibility of causing phosphorus deprivation with a normal dietary. Since there is no evidence in our data that the consumption of a large amount of aluminum can lead to any primarily pharmacologic action in the system, there can therefore be no medical objection to the consumption by human beings of a small amount (relative to the phosphorus content) of added aluminum, as the factor of safety is ample.

SUMMARY AND CONCLUSIONS

1 The aluminum content of fresh tissues of guinea-pigs receiving no added aluminum is about 0.4 part per million or less.

2 The carcasses of growing guinea-pigs on a diet containing no added aluminum have a higher content of aluminum than those of the adult animals.

3 Feeding of large amounts of soluble aluminum salts produces a barely detectable deposition of aluminum in the soft tissues (less than 0.5 part per million) and somewhat larger amounts (from 0.5 to 1 part per million) in carcasses.

4 No systemic pharmacologic effects can be ascribed directly to absorbed aluminum.

5 Aluminum does not appear to be cumulative in the tissues.

6 No harmful effects can be expected from soluble aluminum occurring naturally in foods or introduced by utensils into a diet of normal phosphorus content.

Clinical Notes, Suggestions and New Instruments

HYPERSENSITIVITY TO EPHEDRINE AND EPHETONINE

MICHAEL ZELLER, M.D., CHICAGO

In 1923, Chen and Schmidt recommended the use of ephedrine in the treatment of hay fever, asthma and hypotension. Since then, considerable has been written regarding the therapeutic efficacy of the drug but very little mention has been made of the unfavorable effects that it may produce.

Scheer,¹ in 1929, was the first to report a case of dermatitis venenata of the nose and upper lip resulting from the local application of ephedrine in oil. Ramirez and Eller² observed four cases of contact dermatitis due to ephedrine. In 1931, Ayres and Anderson³ reported similar cases following nasal and oral administration of ephedrine, but their cases presented, in addition, generalized scarlatiniform eruptions. Bullen, Frances and Parker,⁴ in 1932, reported two cases of dermatitis medicamentosa due to ephedrine.

Following is the report of a case of dermatitis venenata due to nasal application of ephedrine inhalant.

REPORT OF CASE

Mrs. L. O., aged 42, seen in 1930, complained of hay fever, which commenced usually about August 15 and continued until frost. Skin tests revealed definite sensitization to the pollens of ragweed and burweed marsh elder, treatment for which was given. A sister and one son have hay fever. Two sons have asthma.

Ephedrine inhalant was prescribed for local relief of nasal symptoms. Following the third application of several drops in each nostril, itching and redness of the nose appeared. Within twelve hours this became increasingly worse, resulting finally in yellow crust formation about the alae nasi and diffuse redness and swelling of the nose. Accompanying the local lesion was a diffuse scarlatina-like eruption, appearing first on the forearms, hands, legs and feet and later on the chest and abdomen. This appeared and disappeared alternately for thirty-six hours and then cleared up completely until, three weeks later, desquamation appeared on the palms of both hands and between the fingers and toes. Intense itching was present over the area of the eruption.

EXPERIMENT

After the eruption had entirely disappeared, ephedrine hydrochloride in three-eighths grain (0.024 Gm.) doses was administered by mouth. Within three hours after the first dose, itching was noted on the flexor surfaces of the elbows and knees and between the fingers and toes.

After the fourth dose twelve hours later a generalized scarlatiniform eruption appeared, associated with swelling, redness and crusting of the nose as before. These manifestations persisted for several days and gradually cleared up. Desquamation appeared again about three weeks after the initial eruption.

Ephetamine (synthetic ephedrine) administered by mouth produced itching of the hands and flexor surfaces of the elbows and knees within three hours after the administration of one tablet. Owing to the severity of the itching and eruption produced by ephedrine, the patient would not consent to further ingestion of ephetamine. Epinephrine hypodermically and locally in the nose produced no symptoms.

Scratch tests with ephedrine applied to the patient's forearm were distinctly positive in three hours. A similar test performed with ephetamine was positive in six hours. Controls in both instances were negative.

Patch tests on the patient done with ephedrine and ephetamine resulted in itching six hours later and within twenty-

³ Ayres Samuel Jr. and Anderson N. P. Dermatitis Medicamentosa Due to Ephedrine. *J. A. M. A.* 97: 437 (Aug. 15) 1932.

⁴ Bullen S. S., Francis N. and Parker J. M. Dermatitis Medicamentosa Due to Ephedrine. *J. Allergy* 3: 485 (July) 1932.

four hours a red scarlatina-like eruption appeared over the area of both patches. This skin response to the local application of ephedrine and ephetonine in the form of patch tests appeared identical to that produced by oral administration of ephedrine. Controls on the patient and nonsensitive individuals were negative.

Passive transfer tests were performed by injecting intradermally the serum of the patient into three normal nonsensitive individuals. After twenty-four hours, scratch tests with ragweed at the sensitized site in one of the normal individuals was positive within fifteen minutes. Scratch tests with ephedrine and ephetonine into the sensitized areas were negative. Controls in the same arm of the normal individuals were negative. Two of the normal individuals were given ephedrine hydrochloride by mouth prior to the experiment, thirty-six hours after the passive transfer, ephedrine hydrochloride in three-eighths grain doses was administered by mouth, but no alteration appeared in the sensitized skin areas.

SUMMARY

1 Patch tests and scratch tests were positive in a case of ephedrine and ephetonine hypersensitivity and appear to be of value from a diagnostic standpoint. The mechanism of the scratch response may have been due to simple contact, as in the patch test.

2 Persons not tolerating the use of ephedrine will probably also prove hypersensitive to ephetonine.

3 Passive transfer tests in a person sensitive to ragweed, ephedrine and ephetonine were positive with ragweed but not with ephedrine and ephetonine.

4753 Broadway

CONGENITAL ATRESIA OF THE ESOPHAGUS A NEW DIAGNOSTIC TECHNIC

GABRIEL TUCKER M.D., AND EUGENE P. PENDERGRASS PHILADELPHIA

The mortality rate, so far as I have been able to determine, is 100 per cent in congenital atresia of the esophagus. Death is not due to starvation in most cases, but to pulmonary complications from the aspiration of secretions and from the return of fluids and foods when a gastrostomy has been done through the lower segment of the esophagus.

The usual method of diagnosis is the administration of a bismuth preparation or barium sulphate with roentgen study. This outlines the pouch, and if the upper segment of the esophagus communicates with the trachea, the mixture passes

Fig 1—Infant bronchoscope within the trachea. An opaque catheter has been introduced through the bronchoscope through the tracheo-esophageal fistula and lower segment of the esophagus into the stomach.

into the tracheobronchial tree. If there is no communication between the upper segment of the esophagus and the trachea, unless great care is exercised there will be an overflow and secretions will be aspirated into the trachea, in many cases contributing largely to the pulmonary complication.

Read before the Section on Laryngology, Otolaryngology and Rhinology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

A female infant 3 days of age was referred to the Bronchoscopic Clinic at the Hospital of the University of Pennsylvania by Dr. Richard Meade of Philadelphia, with a history of inability to swallow and regurgitation of all fluids from birth. The child was apparently well developed and well nourished.

Fig 2—An opaque catheter within the larynx and trachea and lower esophageal segment establishing the diagnosis of congenital atresia of the esophagus, type 3 B.

The following technic was used in examination of the esophagus.

The child was placed on a fluoroscopic table, and all secretions were aspirated from the pharynx and the upper segment

Fig 3—Diagram illustrating the use of the opaque catheter in the differential diagnosis of the types of congenital esophageal atresia. O.C. indicates opaque catheter, T, trachea and E, esophagus. (Adopted from E. P. Vogt.)

of the esophagus. A 35 mm esophagoscope was passed into the upper segment of the esophagus, which was found to terminate in a blind pouch above the level of the suprasternal notch. A small amount of thin bismuth mixture was then given, 1 teaspoonful, and a film was made showing the outline of the upper segment of the esophagus. The bismuth solution was then aspirated from the upper segment of the esophagus. A 35 mm infant bronchoscope was passed, and the lower portion of the trachea was explored. A fistulous tract was found in the posterior tracheal wall, just at the entrance of the left bronchus. A small opaque ureteral catheter was passed through the bronchoscope into the fistulous opening, and under fluoroscopic guidance it was seen to pass into the lower segment of the esophagus and on into the stomach. This established the diagnosis of a communication between the lower end of the trachea and the upper end of the lower segment of the atresic esophagus. Gastrostomy was done by Dr. I. S. Ravdin, and the lower end of the esophagus was tied off. Gastrostomy feeding was carried out, and the child progressed favorably for several days. Pulmonary complications finally developed from aspirated secretions due to overflow and post-mortem examination showed that the closure of the lower end of the esophagus was successful in preventing the passage of fluids from the stomach into the trachea.

CONCLUSION

A case of type 3 A congenital atresia of the esophagus is presented, of the more frequently occurring type A. A method of combined roentgen and esophagoscopy technic is presented for determination of the exact type of atresia and the preven-

tion of aspiration of opaque mixtures into the tracheobronchial tree

It is suggested that, with the establishment of a fistula in the neck from the upper segment of the esophagus, in order to prevent aspiration of secretion, later resection or dilation of the strictured area might be accomplished

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

DIPHTHERIA TOXOID (See New and Nonofficial Remedies, 1933, p 384)

E. R. Squibb & Sons, New York

Diphtheria Toxoid Squibb (See New and Nonofficial Remedies 1933 p 386)—Also marketed in packages of one vial containing 1 cc of diluted diphtheria toxoid for the reaction test.

ANAEROBIC ANTITOXIN (See New and Nonofficial Remedies, 1933, p 359)

The National Drug Co., Philadelphia.

Gas Gangrene Antitoxin Refined and Concentrated—An antitoxic serum prepared by immunizing horses individually against the toxins of *B. perfringens* (*B. welchii*) and *vibrio septique*. After the desired degree of potency is obtained, the horses are bled, the plasma is separated and the serum is prepared in a manner similar to that used for other antitoxic serums. The product is concentrated and refined by a method which is similar to that used for diphtheria antitoxin. The unit values of the constituents are determined according to the method described by the National Institute of Health. Marketed in packages of one syringe containing 10,000 units of *perfringens* antitoxin and 10,000 units of *vibrio septique* antitoxin.

Dosage—The contents of one syringe preferably by intravenous or intramuscular injection repeated in from eight to twenty-four hours as required.

Tetanus Perfringens Antitoxin Refined and Concentrated—An antitoxic serum prepared by immunizing horses individually against the toxins of *B. tetani*, *B. perfringens* (*B. welchii*) and *vibrio septique*. After the desired degree of potency is obtained, the horses are bled, the plasma is separated and the serum is prepared in a manner similar to that used for other antitoxic serums. The product is concentrated and refined by a method which is similar to that used for diphtheria antitoxin. The unit values of the constituents are determined according to the method described by the National Institute of Health. Marketed in packages of one syringe or one ampule vial containing 1,500 units of tetanus antitoxin, 2,000 units of *perfringens* antitoxin and 2,000 units of *vibrio septique* antitoxin.

Dosage—For prophylaxis the contents of one syringe, or ampule vial injected subcutaneously, or intramuscularly, for treatment the contents of three or four ampule-vials or syringes, injected intravenously.

ERYSIPELAS ANTISTREPTOCOCCUS SERUM (See New and Nonofficial Remedies, 1933, p 370)

The National Drug Co., Philadelphia

Erysipelas Antistreptococcus Serum—The serum is obtained from horses immunized with hemolytic streptococci isolated from patients with erysipelas, also with the toxins produced by these organisms. It is concentrated and refined by a method similar to that used for diphtheria antitoxin. Marketed in packages of one syringe containing 10 cc., the average initial therapeutic dose.

DIPHTHERIA IMMUNITY TEST (SCHICK TEST) (See New and Nonofficial Remedies, 1933, p 398)

The National Drug Co., Philadelphia

Schick Test Peptone Diluent—(See New and Nonofficial Remedies 1933 p 400)—For the control test, the product is supplied in single vial packages of 1 cc. and 5 cc. containing respectively sufficient heated diphtheria toxin diluted with peptone solution, for ten and fifty control tests.

TUBERCULIN-KOCH (See New and Nonofficial Remedies, 1933 p 377)

The National Drug Co., Philadelphia

Tuberculin Old (Human)—(See New and Nonofficial Remedies 1933 p 380)—Also supplied on special order in 10 cc. ampule vials of five equal dilutions 1 to 4 representing in each two minims respectively 0.001 mg, 0.01 mg, 0.1 mg, and 1 mg of old tuberculin and dilution 5 representing 10 mg of old tuberculin in each minim.

EPHEDRINE SULPHATE-ABBOTT (See New and Nonofficial Remedies, 1933, p 192)

The following dosage forms have been accepted

Capsules Ephedrine Sulphate Abbott ¼ grain
Capsules Ephedrine Sulphate Abbott ½ grain
Capsules Ephedrine Sulphate Abbott ¾ grain
Solution Ephedrine Sulphate Abbott 5% It is preserved with chlorbutanol 0.5%

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

COLMAN'S MUSTARD

Distributor—Atlantis Sales Corporation, Rochester, N. Y.

Manufacturer—J. & J. Colman, Limited, London and Norwich

Description—A blend of yellow and black mustard flours

Manufacture—Yellow and black mustard seeds are separately graded and cleaned of foreign materials and seeds by the usual commercial processes for cleaning grain and seeds. The seeds are crushed between rolls, the crushed material is sieved to remove the hulls. The resultant finely ground yellow and black mustard flours are blended in definite proportions to maintain a uniform standard product, which is packed in tins.

Analysis (submitted by manufacturer) —

	per cent
Moisture	4.1
Ash	4.4
Acid insoluble ash	0.2
Fat (ether extract)	35.0
Nitrogen	5.4
Protein (nonallyl isothiocyanate N X 6.25)	32.9
Crude fiber	1.0
Copper reducing substances as dextrose by direct acid hydrolysis method	7.3
Allyl isothiocyanate	0.7

Claims of Manufacturer—Conforms to the United States Department of Agriculture standard and definition.

HAWAIIAN FINEST QUALITY PINEAPPLE

(VACUUM PACKED) (CRUSHED, SLICED AND TIDBITS)

(1) DORIS (2) RIVAL, (3) SNOW BALL, (4) HONEY GROVE, (5) WHITE VILLA BRANDS

Packer—Hawaiian Pineapple Company, Ltd., San Francisco

Distributors—1 and 2, Rival Foods, Inc., Cambridge, Mass.
3 G. E. Howard & Company, Newburg, N. Y. 4 and 5, the Cincinnati Wholesale Grocery Company, Cincinnati

Description—Canned pineapple (sliced, crushed and tidbits) packed in concentrated pineapple juice syrup with added sucrose. The same as Dole's 1, 2 and 3 Hawaiian canned pineapple products (THE JOURNAL, April 8, 1933, p 1106, and April 29, 1933, p 1338).

TOWN TALK HIGHEST GRADE FLOUR (BLEACHED)

Manufacturer—Lawrenceburg Roller Mills Company, Lawrenceburg, Ind.

Description—Hard winter wheat short patent flour, bleached

Manufacture—Selected hard winter wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen oxide.

Claims of Manufacturer—An all purpose flour

TOPMOST TOMATO JUICE

Packer—American Packing Corporation, Evansville, Ind.

Distributor—Tibbitts-Henitt Grocery Company, St. Louis

Description—Pasteurized tomato juice with a small amount of added salt, retains in high degree the vitamin content of the raw juice. The same as Loudon Brand Tomato Juice (THE JOURNAL, June 25, 1932, p 2289).

SATURDAY, NOVEMBER 25, 1933

THE MINERALIZATION AND VITAMINIZATION OF MILK

The urge to devise perfect foods was never more compelling among the producers of nutriment than it is at present. The term foods refers here to individual items of the diet rather than to the general regimen, which may comprise a great variety of individual foods. There is a belated but growing appreciation of the fact that nature has not provided any single article of food that alone is adequate or perfect for all persons. Even milk is currently described as "nature's most nearly perfect food," thereby indicating that it has some limitations. Today the science of nutrition is no longer satisfied to speak in terms of proteins, fats and carbohydrates alone. As Professor Sherman¹ remarked in a recent address before the American Chemical Society at Chicago, if something of the order of thirty-odd chemical entities (elements or compounds, as the individual case may be) must be nutritionally supplied to the body from without, besides all the substances that it makes within itself, application of the algebra of combinations and permutations will soon show that a human lifetime would not be sufficient for the consideration of all possible interrelations. Plainly this promises to be almost too fertile a field, a region in which the investigator must guard against losing himself in a jungle growth of interrelationships.

The newer knowledge has begun to stress the special roles of individual inorganic elements—the so-called mineral nutrients. Some of them loom large in importance despite the fact that quantitatively they may be required or desirable in scarcely more than traces, such as a few milligrams of iron or even less of iodine. Other essentials, like the vitamins, also belong in the category of the "little things in nutrition" that count in a large way. Sherman has emphasized that scientifically the vitamins should not go under a group name, for they are not a sufficiently similar or related group of substances. The more one learns about the vitamins, the less alike do they appear. That they have been so

grouped, he adds, is the accidental result of their existence having been discovered and their nutritional importance established in too rapid a succession for the actual physical isolation and complete chemical identification of the substances to keep pace, even though many able chemists have been working actively on the pure chemistry of these compounds.

The unique significance of milk in the American dietary offers the excuse—or perhaps one should say the reason—for attempting to improve it nutritionally as well as from a sanitary standpoint. Even the question of pasteurization has not passed entirely beyond the stage of debate in some quarters. The "modification" of milk, notably for infant feeding, has long been practiced. Originally this involved abstraction of certain components, such as the cream with its richness in fats, the dilution of milk with water, or the combination of dilution with addition of carbohydrate or energy-yielding products. Recent proposals include what have been called the "mineralization" and the "vitaminization" of milk.² It may properly be asked whether the addition of inorganic compounds and vitamin products to market milk as it is ordinarily produced is justifiable.

In attempting to answer this question, Krauss² of the Ohio Agricultural Experiment Station at Wooster has pointed out that mineralization of milk has confined itself to the three elements iodine, iron and copper. Advocates of iodine and of products containing iodine are urging the use of this element in the feeding of dairy cattle, not only because of any benefits the cow may receive but because of the resulting "iodized milk," which may help to solve the goiter problem. Demonstrations made in many laboratories showing that milk is deficient in iron and copper have led many to believe that these two minerals need to be added to milk. With reference to iodine, Krauss believes that the goiter problem is sufficiently complicated already without introducing into the field another material containing iodine, in which the amount of iodine is difficult to control and more difficult to determine. It would seem to be a function of a group of investigators in dairy problems, he believes, to study the fundamentals of the production of iodized milk and to determine the iodine content of market milk in order to allow the medical profession to be guided in its course of action along therapeutic lines. For the present one may disregard the problem of fortifying milk with iron and copper for the infants that have a considerable storage of iron and copper which serves to tide them over until the time when foods with an adequate content of iron and copper can be added to the diet. From the adult standpoint, Krauss contends, the fortification of milk with iron and copper would seem to be an entirely superfluous procedure, except in the treatment of certain

² Krauss, W. E. Should the Mineralization and Vitaminization of Milk Become General? *Bimonthly Bull. 164 Ohio Agric. Exp. Sta.* 18 (126 (Sept-Oct) 1933).

anemias in which it is desired to administer iron and copper through the medium of milk

Recorded assays show that milk may be rated as an excellent source of vitamin A, a fair to good source of vitamin B, a variable source of vitamin C, a poor source of vitamin D and an excellent source of vitamin G, and that it contains vitamin E. The feed of the cow plays an important part in determining the amount of each vitamin, except B and G, in milk. Most authorities will agree with Krauss that the haphazard addition of all sorts of vitamins and mineral elements to milk would jeopardize the unique and excellent position now enjoyed by this product in the eyes of the general public and the medical profession. Krauss's conclusions deserve widespread quotation. In spite of the intriguing mystery and glamor that surround some of the newer discoveries in nutrition, he states, the fact must not be lost sight of that plain, ordinary milk is the best single food available and is thus considered by all. The fact that a sufficient intake of calcium cannot be obtained except by the inclusion in the diet of some form of milk or cheese places these dairy products on a pedestal by themselves. However, the incidence of rickets is still greater than it need be. In the past, dependence has been placed on such antirachitic agents as cod liver oil, viosterol and sunshine, natural and artificial. It is not because of the ineffectiveness of these sources of vitamin D that rickets still exists. Rather, it is because of insufficient or unfaithful use of these materials, for which condition parents are probably chiefly responsible. Whatever the explanation may be, the fact remains that the incidence of rickets is still too great and will continue to be until some cheap, generally available, agreeable source of vitamin D is provided. Vitamin D milk seems to offer promising possibilities of meeting these requirements.

TUBERCULOUS BACILLEMIA

Interest in tuberculous bacillæmia has been renewed because of the clear discrepancies in recent studies of blood cultures. The work of Löwenstein¹ and his associates has been disappointing, since most other investigators using Löwenstein's technic have obtained contradictory results. Löwenstein obtains cultures of tubercle bacilli from the blood by centrifugating from 8 to 10 cc of the citrated blood, destroying the erythrocytes with 3 per cent acetic acid and, after washing in distilled water, inoculating the sediment on tubes of Löwenstein's asparagin egg medium. Löwenstein examined in this manner more than 4,000 cases and reported that tubercle bacilli are present in the blood of patients suffering from progressive forms of tuberculosis (from 39 to 100 per cent), renal tuberculosis (59 per cent), laryngeal tuberculosis (55 per cent),

miliary, meningeal and intestinal tuberculosis (from 80 to 100 per cent), acute and chronic polyarthritis (67 per cent), chorea, multiple sclerosis, schizophrenia, and retrobulbar neuritis (48 per cent). The finding of tubercle bacilli in the blood in chorea, polyarthritis and multiple sclerosis was quite unexpected and required explanation.

Since 1930, many investigators have been unable to confirm Löwenstein's work. Wilson² has subjected the entire question to a critical review and has exposed numerous fallacies in technic, which should be avoided hereafter in all examinations for the tubercle bacillus. Acid-fast bacilli are found in commercial distilled water, in reagents made up with distilled water, in tap water, in metal taps, on leather and rubber washers, and in preparations of pepsin and trypsin. Saprophytic acid-fast bacilli occur in dust, milk, grass, smegma, butter, manure, soil, human feces and blood, and in the intestinal contents of insects. Many types of saprophytic acid-fast bacilli cannot be distinguished morphologically from the tubercle bacillus. Another source of error is the presence of artefacts due to fibrin threads, hemin crystals, ovalate crystals, partly disintegrated leukocytic granules, lipid portions of the erythrocyte envelop, and crystals of lecithin and cholesterol.

Still another source of error may be the technic and interpretation of animal inoculations. Many observers have failed to exclude spontaneous tuberculosis, pseudotuberculosis, *Salmonella* and *Alcaligenes* infections, and occasionally pyogenic infections that may cause lesions simulating tuberculosis. In only 32 of 512 cases reported in which examination was made by animal inoculations may the results be regarded as positive. Critical study of the results of animal inoculation indicates that genuine tubercle bacilli have been demonstrated in the blood in about 4.9 per cent of patients with severe pulmonary tuberculosis, 36.4 per cent of patients with miliary or meningeal tuberculosis, and 27 per cent of patients with nonpulmonary tuberculosis. Wilson, commenting on Löwenstein's figures, maintains that his criteria for identification of the tubercle bacillus are inadequate and subject to the technical fallacies just stated. In work subsequent to Löwenstein's, 5,573 blood cultures from tuberculous and nontuberculous patients yielded tubercle bacilli in 72 instances. Although rare in the early stages of pulmonary and nonpulmonary tuberculosis, a bacillæmia may occur in from 5 to 10 per cent of patients with severe advanced pulmonary tuberculosis and in from 30 to 40 per cent of those with miliary and meningeal tuberculosis.

Wilson states that there is no reliable evidence that a tuberculous bacillæmia occurs in articular rheumatism, polyarthritis, chorea, multiple sclerosis, schizophrenia, retrobulbar neuritis or Hodgkin's disease, nor is there any reason for implicating the tubercle bacillus as an

1 Löwenstein E. Das Vorkommen der Tuberkelbazillämie bei verschiedenen Krankheiten. München med. Wchnschr. 78: 261 (Feb. 13) 1931. Vergleich der Leistungsfähigkeit von Tierversuch und Kulturverfahren. Zentralbl. f. Bact. (part 1) 123: 510 (Feb. 3) 1932.

2 Wilson G. S. Tuberculous Bacillæmia. Special Report Series 182. Medical Research Council London 1933.

etiologic agent in these diseases. However, tuberculous polyarthritis and articular rheumatism have been described by Poncet.³ Recently Cooperman⁴ reported four cases of rheumatoid arthritis, which, after arthrotomy, study of the tissues and animal inoculations, proved to be tuberculous in nature. This aspect of the question has not received the attention it deserves. Nevertheless, bacillenemia of sufficient severity to be recognized by laboratory methods now in use, except as a transitory occurrence, is but rarely present in tuberculosis until the infection has reached an acute stage, associated with extensive lesions or generalization.

Finally, in any investigation no acid-fast organism should be accepted as the tubercle bacillus until it has been demonstrated conclusively to be such by cultural, morphologic and pathogenic tests, due precaution being taken to avoid all positive external sources of error.

THE CHOICE OF OPERATION FOR DUODENAL ULCERATION

The old controversy as to medical or surgical treatment of peptic ulcer, although not finally settled perhaps, has resulted in a somewhat satisfactory compromise. Many surgeons, among them Horsley,¹ try medical treatment for duodenal ulcer, and if this fails they operate. For gastric ulcer, because of the danger of malignant change, they recommend immediate resort to surgical measures.

The problem remains, however, as to what operation should be performed for duodenal ulcer. A contribution to the solution of this problem is Gaither's² recent survey and report. His conclusions are overwhelmingly in favor of conservative operations such as gastro-enterostomy. Strauss's discussion of Gaither's paper, nevertheless, is good evidence that the adherents of gastric resection in this country will not be downed, and the fairly widespread practice of performing radical resection in the clinics of central Europe is well known. The medical profession in general would welcome more accord among authorities on the question raised. Such accord possibly will be delayed until disputants take into account a factor to which attention has been called but little attention given. This factor is the variability of the pathologic conditions that require treatment.

Sebening³ of Frankfurt-on-Main has shown that the type of gastroduodenal ulceration which prevails in central Europe is not the type which prevails in central North America. It is evident, from his report, that he made his comparison of the two types of lesions while

he was sojourning in this country, thus, he had seen material on both sides of the water. He demonstrated, by means of photographs⁴ taken in Schmieden's clinic, what Konjetzney⁵ had described, that is, the almost constant association, in Germany, of gastritis with duodenal ulcer. The gastric change consists in diffuse inflammation, for the most part ulcerative in nature. This demonstration confirmed an observation made in Germany the year before by Walters and Snell⁶ and tentatively reported by them. It may be that in central Europe economic factors and conditions of medical practice result in patients receiving surgical care later than on this continent. If this is so, duodenal ulcers in central Europe probably are larger and produce more obstruction and consequent gastric trauma. The other factor in the comparison can be more briefly stated. In central North America, involvement of the stomach in association with duodenal ulcer is not a prevaillingly characteristic finding.

It seems apparent, therefore, that gastro-enterostomy and other conservative operations would fail to produce the desired results in a large percentage of cases encountered in central Europe, and that the higher mortality rate that partial gastric resection probably entails must be accepted there. However, in central North America, conservative operations would seem rather generally justifiable, unless it could be shown that recurrent ulcer appears in an undue proportion of cases. Nevertheless, even here a number of surgeons favor radical operation for duodenal ulceration, and surgical thought on the subject is not homogeneous. The United States presents many different environments, and its people belong to different racial groups, which in many regions are somewhat segregated. The patients of one physician may differ greatly from those of another. Unless North American surgeons are thoroughly satisfied that the demonstrated differences between gastroduodenal ulceration as encountered generally in central Europe and generally in central North America cannot be demonstrated when the clientele of one North American surgeon is compared with the clientele of another, further investigation of the possibility might be worth while. The pathologic and biometric study that this would involve might result in accord being reached on the middle ground that no operation is preferable of itself but that choice of operation should be deferred until after exploration and thorough inspection have made known whether or not the stomach is involved. Moreover, it must be recognized that there are variations in the capabilities of surgeons, in operative facilities, and in similar factors. This situation emphasizes again the necessity for individualization by each physician of each patient whom he sees.

Current Comment

VITAMIN C THERAPY

In the majority of cases, guinea-pigs maintained on a diet deficient in vitamin C will develop ulcerative lesions of the intestine, if fed daily doses of tuberculous sputum. If this deficiency diet is supplemented by an adequate amount of tomato juice (vitamin C), however, the animals almost invariably remain free from intestinal tuberculosis. Since the guinea-pig and man are apparently identical in their vitamin C requirements, McConkey and Smith¹ of the New York State Hospital for Incipient Pulmonary Tuberculosis conclude that tomato juice therapy has a verifiable rationale in certain forms of clinical tuberculosis. This conclusion would seem to be timely because of the popular interest in vitamin A as a so-called anti-infective vitamin. Current vitamin charts² suggest that vitamin A (cod liver oil) is the only known vitamin with anti-infective properties. The New York investigators, however, could not verify this much advertised claim. In their hands, sputum-fed guinea-pigs were not protected from intestinal tuberculosis by cod liver oil. They emphasize, however, that this failure is of questionable clinical significance, since man and the guinea-pig are widely different in their normal requirements of vitamins A and D.

Association News

MEDICAL BROADCAST FOR THE WEEK

Talks over Network of the National
Broadcasting Company

The American Medical Association broadcasts each Monday afternoon from 3 to 3:15 Eastern standard time (2 o'clock, central standard time). The subject for Monday, November 27, is "Dodging the Common Cold." The speaker will be Dr. W. W. Bauer, director, Bureau of Health and Public Instruction, American Medical Association. Subjects and speakers for subsequent broadcasts will be announced weekly in THE JOURNAL.

Radio Talks from Station WBBM

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock, central standard time over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

November 28 Give Thanks

November 30 Holiday, no broadcast.

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

December 2 Straight as a Ramrod

THE CLEVELAND SESSION

Application Blanks for the Scientific Exhibit

Application blanks are now available for space in the Scientific Exhibit at the Cleveland Session of the American Medical Association June 11-15, 1934. The Committee on Scientific Exhibit requires that all applicants fill out the regular application form and requests that this be done as early as convenient.

Persons desiring application blanks should address a request to the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

District Meetings—Speakers before the First District Councilor Medical Society at Paragould, October 18, included Drs. Julius Frischer, Kansas City, Mo., on transurethral electrosurgery of the prostate, John H. McCurry, Cash, tularemia, Conley Sanford, Memphis, diagnosis of pernicious anemia, with special reference to atypical forms, and William C. Chaney, Memphis, calcium metabolism and its practical application in the practice of medicine. At a meeting of the Third Councilor District Medical Society, October 19, the speakers were Drs. Silas C. Fulmer, Little Rock, "Classification of Heart Diseases," James A. Warner, St. Louis, "Successful Treatment of Biological Diseases, or Biological Therapy," Carroll C. Turner, Memphis, Tenn., "Emotions and Their Relationship to the Glands of Internal Secretion," Willis C. Campbell, Memphis, "Practical Application of Orthopedic Principles," and Herman W. Hundling, Little Rock, "Uterine Bleeding." The Second Councilor District Medical Society heard the following physicians at its meeting in Batesville, October 9: Howard A. Dishongh, Little Rock, "Symptoms, Diagnosis and Treatment of Undulant Fever," Darmon A. Rhinehart, Little Rock, "Injuries of the Wrist—Clinical Varieties, Anatomical Considerations, and X-Ray Diagnosis," Lee V. Parmley, Little Rock, "Injuries of the Wrist—Their Treatment," and Royal J. Calcote, "Impaired Vision and Blindness of Children." Dr. Frank A. Gray presented a case of Bant's disease. The Eighth Councilor District Medical Society was addressed in Little Rock, November 1, among others, by Drs. Rutherford B. H. Gradwohl, St. Louis on "History of the Blood," Augustus C. Shipp, Little Rock, "Tuberculosis," and Alexander C. Kirby, Little Rock, "Birth Injuries."

CALIFORNIA

Outbreaks of Food Poisoning—Bacterial poisoning in ice cream served at a church supper in Los Angeles, October 11, was held responsible for the illness of more than 100 persons who attended, newspapers reported. Traces of an arsenic insecticide were found in the broccoli served at a dinner in Los Angeles, October 15, causing the illness of more than twenty persons. As the result of this outbreak, a preventive and educational drive on the use of poisonous insecticides as vegetable sprays was begun among gardeners in the state.

Society News—Speakers before the San Francisco County Medical Society, November 14, included Drs. Ralph A. Reynolds and Hermann Becks on "Recent Developments in Paratuberculosis (Pyorrhea) Research," and Ludwig A. Emge "Experimental Studies in Tumor Growth: The Behavior of a Transplantable Benign Rat Tumor During a Period of Five Years." A joint meeting of the Los Angeles Surgical Association and the Los Angeles County Medical Association was addressed, November 10, by Drs. Josiah Morris Slemmons, among others, on "Recognition and Treatment of Ectopic Pregnancy." For the first time in the history of San Francisco, not a single case of smallpox was reported during the past year.

Illegal Practitioner Woelfli Sentenced—Frederick Woelfli was recently sentenced to serve 125 days in the Napa County Jail following his conviction of violating the medical practice act. There is also an abortion charge pending against Woelfli. When he was arrested, photographs of a diploma purporting to show his graduation from Rush Medical College, Chicago, and his licensure in Illinois, were found in his possession. Woelfli claimed that the originals were in the care of "some relative of his." Another photograph was of a diploma headed "Crane Sanitarium, School of Natural Therapeutics," dated Elmhurst, Ill. Sept. 30, 1927, stating that he had completed a course of instruction in "Natural Therapeutics." Of the four persons who signed the Crane diploma, only one, Dr. Milo A. Crane, is a doctor of medicine, according to the records of the American Medical Association. In 1927, Crane was expelled from membership in the Chicago Medical Society for unethical conduct. Neither the sanatorium nor its drugless school is recognized by the Association. That the diploma from Rush Medical College is fraudulent is indicated in infor-

mation from the school pointing out the discrepancies between it and authentic credentials. Investigations are being continued by the California Board of Medical Examiners.

FLORIDA

Examination of School Children—Physical examination of all the school children in Hillsborough County was to have begun early in November, according to newspaper reports. Under arrangements worked out by the county school board, parents will be informed of the physical defects of the children.

State Hospital Overcrowded—A recent executive order forbade the acceptance of any more patients at the state hospital at Chattahoochee until the extreme crowding was relieved, according to newspapers. In an attempt to relieve the congestion, the discharge of about 100 senile patients to their relatives was being considered.

Society News—Dr. Leigh F. Robinson, Fort Lauderdale, has been elected president of the Florida East Coast Medical Society, and Dr. Spencer A. Folsom, Orlando, secretary. The next annual meeting will be held in Orlando. At a meeting of the Midland Medical Society, October 26, Dr. Thomas M. Rivers, Kissimmee, was named president, and Dr. James R. Boulware, Jr., Lakeland, secretary.

ILLINOIS

Personal—Dr. William E. Buxton, West Salem, observed his seventy-fifth birthday, recently. Dr. Buxton has been practicing medicine for fifty years. Dr. and Mrs. Charles D. Gardiner, Grand Tower, celebrated their golden wedding anniversary, October 11.

Chicago

Dr. Hesselstine Awarded Prize—Dr. Henry Close Hesselstine, instructor in obstetrics and gynecology, Division of Biological Sciences, University of Chicago, was awarded the annual prize of \$100 by the Central Association of Obstetricians and Gynecologists for the most meritorious work done by one of its members. This is the second time Dr. Hesselstine has won the prize, this year for his research on "Trichomonas Vaginalis Vaginitis," and last year for a paper on "Gynecologic Fungi Infections in Diabetic Patients."

Society News—The Society of Medical History of Chicago was addressed, November 23, by Drs. James B. Herrick on "Allan Burns, Anatomist, Surgeon, Cardiologist, 1781-1813," and by Hugh T. Patrick on "Three Great Neurologists I Have Known." Speakers before the Chicago Neurological Society, November 16, included Drs. Paul C. Bucy on "Ipsilateral Representation in the Motor and Premotor Cortex" and Mabel G. Masten, Madison, Wis., "Neurogenic Ulcers in Cerebral Lesions (Cushing's Syndrome)." At a meeting of the McDonagh Society for Clinical Research, November 17, among others, Drs. Ernst Pribram and Stanley Fahlstrom spoke on "Studies in Arthritis and Arthrosis." The Chicago Pediatric Society was addressed, November 21, by Drs. George Piness, Los Angeles, on "Food Factors in Allergy of Childhood," and Louis W. Sauer, "Whooping Cough Immunization." Dr. Ernst Kraas, University of Frankfurt, Germany, spoke before the Physiology Journal Club, Northwestern University Medical School, November 16, on "Choice of Operation in the Surgery of the Stomach and Gallbladder." Dr. William G. Rogers, among others, addressed the Chicago Gynecological Society, November 17, on "Rupture of the Fetal Liver," and Drs. Beatrice E. Tucker and Harry B. W. Benaron on "Parasacral Anesthesia in Obstetrics." Dr. Fred L. Adair was elected president. The health division of the Council of Social Agencies was addressed at its annual meeting, November 9, by Drs. Frank J. Jirka, state health officer, Frederick Tice of the Municipal Tuberculosis Sanitarium, and Frederick O. Tonney of the Chicago Board of Health.

INDIANA

Hospital News—The William Ross Memorial Sanatorium, Lafayette, opened its fourth annual short course on tuberculosis, October 24, with Dr. Walter H. Mytinger, superintendent, giving the opening address. Other speakers included Drs. Willis D. Gatch, dean, Indiana University School of Medicine, Indianapolis, and Kennon Dunham, Cincinnati.

Society News—Dr. Howard L. Stitt, Cincinnati, addressed the Dearborn-Ohio County Medical Society in Lawrenceburg, October 26, on "Bronchoscopic Lavage." At a meeting of the Jasper-Newton County Medical Society, October 28, Dr. John H. Warvel, Indianapolis, discussed the importance of the laboratory in diagnosis of disease. Dr. Cyrus C. Sturgis, Ann Arbor, Mich., conducted a seminar on anemia before the Elkhart County Medical Society, November 2.

IOWA

Report of Committee on the University Hospitals—A committee of nine, headed by Dr. Elbert E. Munger, Spencer, was appointed last March by the legislature to investigate the causes and suggest remedies for the waiting list of indigent patients committed but not admitted to the University Hospitals in Iowa. The committee recently submitted a report to the legislature, convened in extra session. The list of waiting patients grew from sixteen Sept. 1, 1927, to 5,238 on Feb. 7, 1933. During the year ended June 20, 1932, there were 8,719 patients admitted to the University Hospitals, with an average hospitalization period of 177 days. There was an average daily number of patients in the hospitals of 4,926. The university is said to graduate each year twenty medical practitioners more than are actually required to care adequately for the sick. The establishment of suitable entrance requirements to reduce the average annual number of graduates to seventy-five was urged. This would reduce the amount of teaching material needed and thereby decrease the expenses of the medical school to the state. Admission to the University Hospitals is now governed by the quota plan, which provides that committed patients be admitted to the hospitals in proportion to the population of the counties of their residence instead of as the laws seem to contemplate, in proportion to the number of commitments. The committee of nine believes that this procedure will ultimately retard the admission of adequate material for the instruction of medical students, since the supervisors might preserve their quota by committing patients requiring a long period of care and provide for the treatment of accident and obstetric cases and those of acute illness in their home communities. In its recommendations, the committee urges that half the basic cost of hospitalization of indigents be charged to the counties of their residence, an adequate investigation to be made under the direction of the county board of supervisors before commitment to determine indigence. In this attempt to reduce the number of patients, the reduction should be made selective so that clinical material needs will not be jeopardized and so that the admission of patients who can be best treated there will not be delayed. The reduction of a physician's examination fee from \$5 to \$3 and the escort's wages from \$3 per day to \$2 is recommended. Principal recommendations of a minority report, not yet submitted, urge the removal of the medical college from Iowa City to Des Moines and advocate the repeal of the adult indigent law. Members of the committee of nine are Dr. Oliver J. Fay, Des Moines, Dr. Walter A. Sternberg, Mount Pleasant, Dr. Arthur W. Erskine, Cedar Rapids, secretary, Senator G. W. Patterson, Burlington, Senator E. R. Hicklin, Wapello, Senator Morris Moore, Walnut, Paul L. Millhone, Clarinda, Representative John Speidel, Washington, and Dr. Munger. These men were appointed by the governor, president of the senate, and speaker of the house of representatives.

KANSAS

Society News—Dr. Claude C. Tucker, Wichita, discussed "Anal Fistula and Rectal Abscess" before the Butler-Greenwood County Medical Society in Augusta, October 13. The Sedgewick County Medical Society devoted its meeting, November 21, to a symposium on lesions of the hip, their diagnosis and cure, the speakers were Drs. Arthur E. Bence, Edwin D. Ebricht and Charles R. Rombold, all of Wichita.

LOUISIANA

Protest Enlargement of Charity Hospital—Representatives of six independent hospitals of New Orleans adopted a resolution, November 3, protesting against the erection of a new twenty-six story building for Charity Hospital, mainly because the proposed plans call for the treatment of pay or part pay patients other than patients suffering from contagious diseases. The board of administrators of Charity Hospital is reported to have applied to the federal public works committee of Louisiana for an allotment of \$9,600,000 for this purpose. The resolution points out that, since the independent hospitals of New Orleans are charitable in purpose and not operated for profit, the inclusion of this service in Charity Hospital would be an invasion into the province of their services, as well as an unprecedented departure from the recognized functions of a state charity hospital. The decentralization of hospital care for indigent patients and provision for their care in smaller hospitals at focal points in the state would permit a decrease in the capacity of the present Charity Hospital, the resolution states, while if they were subsidized independent institutions in New Orleans could care for at least 400 more indigent patients. Copies of the resolution were sent to the

Federal Public Works Board of Louisiana, board of administrators of Charity Hospital proper departments in Washington, D C, Orleans Parish Medical Society, Louisiana State Medical Society, the daily press, Louisiana and American hospital associations, and the *New Orleans Medical and Surgical Journal*. The institutions represented in the resolution were Southern Baptist and French hospitals, Flint Goodridge Hospital of Dillard University, Hotel Dieu, Mercy Hospital-Somat Memorial and Touro Infirmary. A resolution, embodying similar objections, was adopted by the Calcasieu Parish Medical Society.

MASSACHUSETTS

Society News—Dr Winfred Overholser, assistant commissioner of the state department of mental diseases, was elected president of the Massachusetts Psychiatric Society at its recent annual meeting, succeeding Dr Morgan B Hodskins, Palmer. —Dr William D McFee, Boston spoke before the Lawrence Medical Club, October 18, in Lawrence, on "Physiotherapy in Relation to General Practice."

George W Gay Lecture—Dr Robert B Osgood, John B and Buckminster Brown professor of orthopedic surgery, emeritus, Harvard Medical School, Boston, gave the George W Gay Lecture on Medical Ethics at the school, November 2, his subject was "The Theology of Medicine." Dr John Homans, assistant professor of surgery spoke, November 9, on "The Care of the Patient" and Dr Elliott P Joslin, clinical professor of medicine, discussed the same subject, November 16.

MICHIGAN

Society News—A symposium on the treatment of fibroid tumors and bleeding during the menopause was presented before the Wayne County Medical Society, Detroit, November 13, by Drs John T Murphy, Toledo, and Jean P Pratt and George A Kamperman, Detroit. A symposium on peptic ulcer was given before the society, November 20 with Drs Patrick L Ledwidge, Osborne A Brines, Clyde E Vreeland, George E McKean, all of Detroit, and Ambrose L Lockwood, Toronto, as the speakers. —The Detroit Obstetrical and Gynecological Society was addressed, November 7, by Drs Charles E Boys, Kalamazoo, on "Role of Supravaginal Hysterectomy in Gynecology, with Motion Picture Illustration of Author's Technique," and Howard H Cummings, Ann Arbor, "Weight Changes During Pregnancy." —At a meeting of the Detroit Pediatric Society and the American Academy of Pediatrics, December 6, Dr Louis H Newburg, Ann Arbor, will speak on nutrition.

Conference on Preventive Medicine—The establishment of a whole time county health departments and the extension of preventive medical procedures into the offices of all cooperating physicians were the subjects of discussion at a state conference of the committee on preventive medicine of the Michigan State Medical Society in Detroit, November 15. Discussing these subjects were Drs Henry A Luce, speaker, house of delegates, state medical society, Stuart Pritchard of the Kellogg Foundation, Battle Creek, Louis J Hirschman, state advisory council, James D Bruce, University of Michigan Medical School, Ann Arbor, Bruce C Lockwood, Wayne County Medical Society, Albert M Wehenkel, and Henry F Vaughan, Dr PH, health commissioner of Detroit. Conferences on communicable diseases and tuberculosis were held in the morning. During the day the public health committee of the Wayne County Medical Society demonstrated how it serves to coordinate and supervise the health services which are a joint concern of the organized medical society and the department of health. The participation of cooperating physicians was shown by the East Side Medical Society of Detroit and the W K Kellogg Foundation demonstrated its application of the medical participation plan in Barry, Eaton and Allegan counties, where conditions are typically rural.

MINNESOTA

Society News—Speakers before the Hennepin County Medical Society, November 1, were Drs Walter J Marcle and Jay Arthur Myers, Minneapolis, on diagnosis of tuberculosis and pneumothorax, respectively, November 6, Dr John S Lundy, Rochester, special methods of anesthesia. November 8, Drs Harold S Diehl and Frederic C Rodda, Minneapolis, medical treatment of the common cold and the acute cold in infancy, respectively. Dr Louis M Warfield, Milwaukee will address the society in Minneapolis, December 4 on "Does the Heart Fail in Acute Infection." The society heard Leroy S Palmer, PhD, professor of agricultural biochemistry, University of Minnesota, speak on the chemistry of foods with special reference to malnutrition and obesity, Drs James B Carey

and Chauncey A McKinley discussed malnutrition and obesity, respectively. —The Minnesota Academy of Medicine was addressed November 8 by Drs Arthur E Smith, Minneapolis, and Alexander R Colvin, St Paul on "The Eye in Cardiovascular Disease" and "Experiences in Surgery of the Colon," respectively.

NEBRASKA

Society News—Dr Leonard J Owen, among others, addressed the Lancaster County Medical Society, Lincoln, October 17, on "Allergic Manifestations of the Skin." —At the October meeting of the Madison S Co. Medical Society in Norfolk, Drs Abram E Bennett and Leon S McGoogan, Omaha, spoke on epidemic encephalitis and purpura in pregnancy, respectively. —Harry N Boyne, DDS, Council Bluffs, and Dr Richard Young, Omaha, addressed the November meeting of the Otoe County Medical Society, Nebraska City, on "Early Diagnosis and Eradication of Oral Pathology" and "Pernicious Anemia Neurologic Complications and Treatment" respectively. —Drs Ira H Dillon and Ernest H Decker, Topeka, Kan, among others, addressed the autumn meeting of the Third Councilor District Medical Society, Humboldt, October 19, on "Interpretation and Treatment of Subjective Eye Symptoms" and "Diagnosis and Treatment of Common Skin Diseases," respectively. —A symposium on pneumonia was presented before the Omaha-Douglas County Medical Society, November 14, by Drs Frank M Conlin, Joseph A Weinberg, Howard B Hunt, Wilson B Moody, Abraham S Rubnitz and James P Tollman.

NEW JERSEY

Society News—Dr Howard Fox, New York, addressed the Bergen County Medical Society, October 10, on "Diagnosis and Treatment of Some Common Skin Diseases," and the county medical relief plan was discussed. —Dr Benjamin F Buzby, Camden, addressed the Gloucester County Medical Society, Pitman, September 21, on osteomyelitis.

Cancer Week in Newark—Exhibits and lectures on cancer for both the medical profession and the public, December 5-7, will mark the observance of Cancer Week by the Essex County Medical Society in Newark at the Academy of Medicine of Northern New Jersey. At a public meeting the evening of December 5, speakers will be Drs Jonathan M Wainwright, Scranton, Pa, chairman of the cancer commission of the Medical Society of Pennsylvania, on "What Has Been Done and What Can Be Done in Cancer Control," Edward J Ill, Newark, "Progress of Our Cancer Knowledge," and William H Areson, Upper Montclair, "Reasons for Cancer Control." The regular meeting of the county society will be held December 7, with Dr Harrison S Martland, medical examiner of Essex County as the speaker, on the present status of theories of the cause of cancer and on metastasis. About fifty exhibits will be presented by individual physicians and eighteen by hospitals.

Annual Health Review—Death rates for tuberculosis, typhoid and diphtheria and infant mortality reached new low records for New Jersey during the year ended June 30, 1933 according to *Public Health News* for October. The rate for diphtheria was 0.02 per thousand of population, for typhoid, 0.006, and for tuberculosis, 0.6. The infant mortality rate was 50. A new law regulating production and handling of milk products was put into effect during the year and minimum standards of sanitation for roadside food stands and similar places were adopted. The first year under a law requiring dog bites to be reported to local health authorities brought records of 7,809 persons bitten. Among the dogs were 222 affected with rabies three of the victims died. Laboratory service was greatly increased during the year according to the report. A 57 per cent increase in the number of samples of water and sewage tested was reported. More than 41,000 Wassermann tests were made. A new law places on the department the duty of licensing barbers and inspecting barber shops.

NEW MEXICO

State Health Survey—Carl Buck, Dr PH, field representative of the American Public Health Association, is beginning a health survey of New Mexico under the auspices of the New Mexico Tuberculosis Association. The survey has been endorsed by the New Mexico Medical Society and other health organizations and the U S Bureau of Indian Affairs and the American Social Hygiene Association are cooperating in the work. Dr Walter J Clarke, New York, of the latter organization has begun work on the social hygiene aspects. A one-day census of venereal disease under treatment is to be made December 1, with the cooperation of the U S Public Health Service.

NEW YORK

District Meeting—The annual meeting of the Second District Branch of the Medical Society of the State of New York was held in Garden City, November 16. A symposium on acute conditions in the abdomen was presented from the points of view of the surgeon by Drs. John E. Jennings, Brooklyn, and James Wesley Bulmer, Glen Cove, the internist, by Drs. Carl Boettiger, Long Island City, and Irving Gray, Brooklyn, the gynecologist, by Dr. Charles A. Gordon, Brooklyn, the urologist, by Dr. James W. McChesney, Baldwin, the neurologist, by Dr. Orman C. Perkins, Brooklyn, and the pediatrician, by Dr. Miner C. Hill, Oyster Bay. Dr. William W. Bauer, director, Bureau of Health and Public Instruction, American Medical Association, Chicago, gave an address at the evening banquet on control by the medical profession of the practice of preventive medicine.

New York City

Second Harvey Lecture—William Mansfield Clark, Ph.D., De Lamar professor of physiologic chemistry, Johns Hopkins University School of Medicine, Baltimore, delivered the second Harvey Lecture at the New York Academy of Medicine, November 16, on "The Potential Energies of Oxidation-Reduction System and Their Biochemical Significance."

Hospital News—A symposium on medical education was presented at Mount Sinai Hospital, November 6, by Drs. G. Canby Robinson, John H. Wyckoff, Jr., and Willard C. Rappleye. Beth Israel Hospital and the Jewish Maternity Hospital have merged to form what will be known as the Beth Israel Medical Center. Maternity Hospital is to have a new building adjacent to the comparatively new building of Beth Israel.

Dr. Welch Retires as President of Rockefeller Board—Dr. William H. Welch, Baltimore president of the board of scientific directors of the Rockefeller Institute for Medical Research since it was founded in 1901, has retired. He was elected member emeritus of the board a new office. Dr. Welch is now 83 years old. Dr. Theobald Smith, Princeton, N. J., director emeritus of the department of animal pathology of the institute, succeeded Dr. Welch.

Society News—The section on orthopedic surgery of the New York Academy of Medicine held a joint meeting with the Orthopedic Club of Philadelphia, November 17. Drs. Arthur Bruce Gill and James T. Rugh, Philadelphia, presented papers on "Treatment of Intracapsular Fractures of the Neck of the Femur" and "Injurious Effects of Menstruation on Inflammatory Joint Processes," respectively. Dr. Francis Carter Wood addressed the New York Roentgen Society, November 20, on "Recent Studies on the Etiology of Cancer." A symposium on gastric neoplasms was presented at a joint meeting of the section on surgery of the New York Academy of Medicine with the New York Pathological Society, November 23, by Drs. Arthur Purdy Stout, Ross Golden and Fordyce B. St. John. Dr. Nathan B. Van Etten addressed the Medical Society of the County of Queens, October 31, on "Problems of the Young Physician." A round table conference on diabetes mellitus made up the program of the Medical Society of the County of New York, October 30. Speakers were Drs. Rollin T. Woodyatt, Chicago, Priscilla White, Boston, and Herman O. Mosenthal and Henry Rawle Geyelin, New York.

OHIO

Charity Surgical Treatment Limited to Emergencies—The council of the Toledo Academy of Medicine at a recent meeting passed a resolution recommending a limitation of staff service in Toledo hospitals to acute emergency operative cases during the economic depression. The matter was referred to the academy's hospital relations committee, which endorsed the council's policy and recommended that any physician who did not adhere to the spirit of the decision be requested to resign from the academy. The eye, ear, nose and throat section of the society almost unanimously signed a pledge to do no more "routine" but only emergency surgery in the hospital clinics.

PENNSYLVANIA

Society News—A symposium on cancer was presented at the meeting of the Dauphin County Medical Society, Harrisburg, November 7 by Drs. Justin Loomis Christian, Park A. Deckard, Harvey F. Smith, William M. Kunkel and George R. Moffitt. The Western Pennsylvania Eye, Ear, Nose and Throat Society was organized at a meeting in Indiana, October 19. Drs. George M. Coates, Philadelphia, and George H. Shuman, Pittsburgh, addressed the meeting on sinus disease and slit lamp microscopy, respectively. Drs. Charles Geschickter

and Murray M. Copeland, Baltimore, addressed the Fayette County Medical Society, Uniontown, November 2, on tumors.

Advisory Committees—The mayor of Pittsburgh some months ago appointed an advisory committee on health problems, which has now outlined its program of study and chosen subcommittees (THE JOURNAL, May 13, p. 1549). The problems selected for study and the chairmen of committees are air hygiene, Dr. Samuel R. Haythorn, venereal disease control, Dr. Charles B. Schildecker, water control, C. F. Drake, superintendent of the filtration plant, Negro health, Dr. George E. Martin, housing survey, Mr. Charles F. Lewis, director of the Buhl Foundation, preschool child health, Dr. Carl K. Wagener, municipal waste disposal, and squatter control. Committees for the last two subjects named have not been announced.

Philadelphia

Hospital News—A new unit of the Philadelphia Skin and Cancer Hospital was opened, October 5. Dr. Albert Strickler is medical director. The federal public works administration has allotted \$2,250,000 for completion of the Naval Hospital. It is now about one third finished.

Society News—The program of the Philadelphia County Medical Society, November 22, was devoted to consideration of minor surgical conditions met by the general practitioner. Speakers were Drs. Eldridge L. Eliason, on "Finger Infections," Edward T. Crossan, Acute Ankle Sprains, and George P. Muller, "Cervical Adenitis." Dr. Myer Solis Cohen, among others, addressed the Philadelphia Pediatric Society, November 14, on "Acute Interstitial Pneumonia A Peculiar Form Not Mentioned in Textbooks," with report of eight cases.

TEXAS

Directory of Licensed Physicians—The Texas State Board of Medical Examiners has published a directory of all licensed physicians in the state as of October 1. It is planned to publish such a list each year, according to Dr. Thomas J. Crowe, Dallas, secretary of the board. The booklet is available for 25 cents per copy, to cover cost of printing and mailing.

District Meeting—The Northwest Texas District Medical Society and the Fort Worth Medical and Surgical Clinics held a joint meeting in Fort Worth, October 10-11. Clinics were held at St. Joseph's, Methodist and the City-County hospitals and addresses were given, among others, by Drs. William B. Carrell, Dallas, "Prevention of Deformity Following Polymyositis," John Harold Turner, Houston, "Prostatic Resection Indications and Limitations," and George V. Brindley Temple, "Complications of Peptic Ulcer." Drs. Bransford Lewis, St. Louis, and Paul M. Bassel, Temple, made addresses at an evening banquet on "Vocations and Avocations of the Doctor" and "Narcolepsy," respectively.

Society News—Drs. Charles W. Stevenson, Wichita Falls, and Roy L. Fisher, Frederick, Okla., addressed the Wichita County Medical Society in Wichita Falls, September 12, on epidemic encephalitis and sacrococcygeal tumors, respectively. Dr. Thomas H. Cheavens, Dallas, addressed the Ellis County Medical Society, Waxahatchie, in September, on the brain and the nervous system. Drs. Edward H. Schwab, Jr., Galveston, and Samuel D. Weaver addressed the Dallas County Medical Society, October 24, on treatment of craniocerebral injuries and hypertension, respectively. Dr. Philip C. Jeans, Iowa City, was guest speaker at a meeting of the Texas Pediatric Society, October 28, in San Antonio, on "Practical Aspects of Nutrition in Childhood." Dr. Quintman U. Newell, St. Louis, addressed the Texas Association of Gynecologists and Obstetricians at San Antonio recently, on advances in the management of sterility and the Harris County Medical Society, Houston, on the prevention of uterine cancer. Dr. Alfred I. Folsom, Dallas, was elected president of the Texas Surgical Society at its semiannual session in Fort Worth, October 16-17. Dr. Hugh H. Trout, Roanoke, Va., was a guest speaker on "Modern Methods of Surgery to Relieve Adhesions Around the Heart."

WEST VIRGINIA

Society News—Dr. Charles Geschickter, Baltimore, addressed the Ohio County Medical Society, Wheeling, November 3, on "Tumors of the Breast." Dr. Louis H. Clerf, Philadelphia, spoke, November 17, on "Diagnosis and Treatment of Pulmonary Abscess and Bronchiectasis." Dr. William R. Laird, Jr., Montgomery, addressed the Fayette County Medical Society, Oak Hill, October 10, on etiology and pathology of acute appendicitis. At a joint meeting of the Parkersburg Academy of Medicine and the Cabell County Medical Society

in Parkersburg, October 5, Drs Frank C Hodges and John H Steenbergen, Huntington, discussed sudden cardiac deaths and office practice of gynecology, respectively—Dr Arthur E McClue, state health commissioner, addressed the Mercer County Medical Society, Bluefield, October 26, on problems of public health work in relation to private practice of medicine

GENERAL

Physical Therapy as Related to Proctology—A committee has been organized by the American Proctologic Society to investigate the status of physical therapy as it applies to proctology. Dr Herbert I Kallet Detroit, has been named chairman, and other members of the committee include Drs Harry Z Hylshman, Philadelphia, Emmett H Terrell, Richmond, Va., E Jay Clemons, Los Angeles, and Frank C Yeomans, New York.

Conference on Birth Control and National Recovery—A three day conference on birth control and national recovery will be held in Washington, January 15-17, under the auspices of the National Committee on Federal Legislation for Birth Control. The preliminary program lists the following subjects for discussion: population problems, religion and moral questions, the family and community welfare, health and economic recovery, contraceptive technique and standards, birth control clinics and federal legislation.

Change of Status in Licensure—The Georgia State Board of Medical Examiners reports the following:

Dr William A. Starnes, Atlanta, license revoked, October 12 for violation of the Harrison Narcotic Act.

The State Board of Health of Kentucky reports the following action:

License of Dr Earle J. Brashear, North Pleasureville, revoked for violation of the Harrison Narcotic Act.

The Colorado State Board of Medical Examiners reports the following action:

Dr Taber A. Darling, Fort Lupton, license revoked October 3 for the unlawful sale of narcotics.

The California State Board of Medical Examiners reports the following action:

Dr Rudolf I. Rohlfing, Los Angeles, license revoked following a hearing on charges that he practiced under a name other than his own. Dr Rohlfing was connected with the Special Cancer Clinic in Los Angeles.

Neuropsychiatric Meeting—The Central Neuropsychiatric Association held its annual meeting in Cleveland, October 13-14, at the Cleveland Clinic and the Lakeside Hospital, where Cleveland members demonstrated their clinical and research facilities and activities. Among the presentations were:

Dr Wallace B. Hamby, Tumors of the Spinal Canal in Childhood
Dr Ursus V. Portmann, X-Ray Treatment of Brain Tumors
Dr John H. Nichols, Congenital Cerebral Atrophy
Dr Richard E. Stout, Psychoses of Myxedema
Dr James D. Filcher, Erythroblastosis Neonatorum Showing Kernicterus
Dr Albert T. Steegmann, Recent Contribution to the Histopathology of Epilepsy
Dr Samuel C. Lindsay, Neuropsychiatric Trends

Dr Hans H. F. Reese, Madison, Wis., made his address as retiring president at the annual dinner and Dr T. Wingate Todd, Cleveland, spoke on "Neuropsychologic Expressions of Infantile Disorders." Dr H. Douglas Singer, Chicago, was elected president and Dr Henry W. F. Woltman, Rochester, Minn., secretary.

Decrease in Number of County Health Units—According to *Public Health Reports* in a discussion of full time health service in rural areas during the period Jan. 1, 1932-Dec. 31, 1932, a net loss of thirty-five full time health units was recorded during the year, when this service was established in nine units and discontinued in forty-four. The largest gain in one state was that of four units in Michigan, while the greatest loss was sustained in Oklahoma, where all nine counties in the state having this service discontinued it. Delaware led in the percentage of rural population under full time health service, all three of its counties having been provided with local full time health organization by the state. Of the states in which the local governmental units maintain the health organizations with or without assistance from the state health department or other sources, Maryland had the highest percentage (95.3) of rural population under full time health service. Of the 581 counties, townships or districts with full time health service, 551, or 94.8 per cent, were receiving financial assistance from one or more of the following agencies: the state board of health, the U. S. Public Health Service, the Rockefeller Foundation, the American Red Cross, the American Women's Hospital Fund, the Rosenwald Fund, the Commonwealth Fund and the Milbank Fund. On Dec. 31, 1932, there were twelve states which did not have local full time health service.

Medical and Surgical Association of the Southwest—The nineteenth annual meeting of the Medical and Surgical Association of the Southwest will be held in El Paso, Texas, December 7-9 at the Hotel Hussman. Discussions for the first day will be on allergy, for the second on tuberculosis, and for the third, on goiter. Among physicians who will deliver addresses are:

Orville H. Brown, Phoenix, Ariz., Food Allergy
Redford A. Wilson, Tucson, Ariz., Hay Fever
James E. Sherman, El Paso, Allergy in Tuberculosis
Warner Watkins, Phoenix, Chronic Inflammation in the Lungs with Special Reference to Silicosis
John Rosslyn Earp, Santa Fe, N. M., Childhood Tuberculosis as a Public Health Problem.
Charles W. Mills, Tucson, Treatment of Cavities
Sturley C. Davis, Tucson, Hypothyroidism
John W. Cathcart, El Paso, X-Ray and Radium Treatment of Exophthalmic Goiter
Gottlieb Werley, El Paso, The Heart in Thyroid Disease

Dr Martin B. Tinker, Ithaca, N. Y., will be the guest speaker, on "Tuberculosis and Malignancy of the Thyroid." Thursday evening, December 7, there will be a clinical demonstration at William Beaumont General Hospital and the annual dinner will be held Friday evening, when Dr. Walter A. Gekler, Albuquerque, N. M., the incoming president, will make his official address.

CANADA

Officers of Medical Council—Dr Robert H. Arthur, Sudbury, Ont., was recently elected president of the Medical Council of Canada, succeeding Dr W. A. Thomson, Regina. Dr Walter S. Galbraith, Lethbridge, Alta., was elected vice president and Dr John Fenton Argue, Ottawa, registrar.

Personal—Dr Robert E. Wodehouse, Ottawa, has been appointed deputy minister of pensions and national health. Dr Wodehouse was at one time a district medical officer of health in Ontario and was recently executive secretary of the Canadian Tuberculosis Association. He succeeds Dr John A. Amyot.

Neurological Institute at McGill—The governor general of Canada, Lord Bessborough, laid the cornerstone of the new Neurological Institute at McGill University, Montreal, at the annual ceremonies on Founder's Day, October 6, the birthday of James McGill. Various donors have provided the fund for building of the institute, the largest among them being the Rockefeller Foundation, which contributed \$1,232,652. Dr Wilder G. Penfield, professor and head of the department of neurology at the university faculty of medicine, is to be head of the institute (THE JOURNAL, June 18, 1932, p. 2220).

Society News—Dr Ernest L. Garner, Vancouver, B. C., addressed the Vancouver Medical Association October 3, on fractures, and Dr Frederic J. Brodie, November 7, on injuries to the brain. Dr James C. McMillan, Winnipeg, was elected president of the Manitoba Medical Association at the annual meeting in Winnipeg, September 7-9. Guest speakers included Drs Roscoe R. Graham, Toronto, on "Surgical Therapy in Biliary Disease" and John C. Meakins, Montreal, "Bronchiectasis and Its Treatment." Dr Thomas A. Ledbetter, Yarmouth, was elected president of the Nova Scotia Medical Society at the annual meeting in Halifax, September 5-6.

Government Services

Federal Malaria Control

Ten million dollars will be expended in the federal program of malaria control to be launched by the U. S. Public Health Service this month, it is reported. The work will be carried on in twelve states: Florida, Arkansas, Alabama, Louisiana, the southeastern portion of Missouri, Mississippi, North Carolina, South Carolina, Georgia, Tennessee, Texas and Virginia. Dr Thomas H. D. Griffiths, who has been conducting a preliminary survey in Florida for the past year, will supervise the campaign, which is planned to begin in the counties of western Florida. The plan, approved by the Federal Emergency Relief Administration, provides that while the public health service will cooperate in technical direction and will detail medical and engineering officers for duty in the states, each state department of health is ultimately to assume direction of the work. Surveys conducted by Dr Griffiths in eight of the most heavily infected counties in Florida reveal that more than 5 per cent of the 10,000 school children examined have shown malarial infection; this number not including those who were actually suffering from acute attacks of malarial fever.

LONDON

(From Our Regular Correspondent)

Nov 4, 1933

The Control of Measles

The London County Council, which now controls almost all the hospitals for infectious diseases in the metropolis, has issued a comprehensive report on the measles epidemic of 1931-1932, in which is shown the value of the recently introduced serum treatment both as a prophylactic agent and in the attenuating of attacks. About six years ago, several animal serums were available for the treatment of measles. A trial of three of these was made and the results were compared with those of the serum of human convalescents in preventing the disease. Injection of the three animal serums into susceptible "contacts" was followed by the development of measles in 57, 60 and 100 per cent of the cases, respectively, while injection of human convalescent serum was followed by measles in only 43 per cent. As a result of these experiments the use of animal serum was abandoned in the London fever hospitals and it obtained no vogue in this country. The haphazard way in which various so called immune serums have been administered in measles prophylaxis on the European continent is open to criticism. On the one hand, sufficient care is rarely taken to ascertain whether effective exposure to measles has taken place or whether the patient has had a previous attack, and, on the other hand, control experiments are usually inadequate or are omitted altogether. In the earlier experiments in London, alternate contacts of approximately the same age, who occupied beds at similar distances from the infecting patient, were inoculated with doses adjusted to body weight, but even then unexpected and uneven results were encountered, depending on such variables as different bed spacing, season, duration of the exposure, degree of catarrh in the primary case, and nursing efficiency. To insure a sufficient margin of safety a dosage scheme more generous than that recommended by most continental and American workers was adopted. A minimum injection of 5 cc of serum was given, and from three years onward the dose was reckoned in cubic centimeters by multiplying the age in years by 2. This increased dose was given to overcome the occasional discrepancy between body weight and age, as probably the final concentration of antibodies in the circulation is the factor that determines success. The injections were given intramuscularly as soon as possible after the contact, certainly before the sixth day, if complete protection was desired. If attenuation was aimed at the same dose was given between the sixth and the ninth day, or half the dose was injected in the first five days, with similar results and economy in the use of serum. With the doses mentioned, complete protection resulted in the last hundred prophylactic inoculations.

POOLED ADULT SERUM

As adequate supplies of convalescent serum were not available when needed most, a supply of pooled adult serum was organized and its value ascertained. An appeal for blood was made to the medical and nursing staffs of the council's hospitals. Great care was taken to make certain that the history of a previous attack of measles was authenticated. Nevertheless from 3 to 5 per cent of the donors had never had the disease. On the other hand, as they were actively engaged in infectious disease work and subject to contact with measles patients, the antibody content of their blood was probably above the average. Comparison was made between 1475 cases in which adult serum was injected and 680 cases in which convalescent serum was injected. The figures were analyzed by an expert statistician.

Mr W T Russell, of the department of statistics at the London School of Hygiene and Tropical Medicine. Convalescent serum was found to be a more powerful prophylactic than adult serum for each age group, but the difference was of statistical significance only in respect to children under the age of 5 years and was greatest in the age group of 1 to 3 years, at which period susceptibility is highest. After the age of 5 years there was nothing to choose between the two serums.

It was found that protection could almost certainly be obtained if, during the first three days after exposure, 4 cc. of adult serum or 2 cc of convalescent serum, multiplied by the age of the child, was injected intramuscularly, with minimum doses of 10 cc and 5 cc, respectively. Attenuation was more problematic. If these doses were given from the sixth to the ninth day, attenuation followed in only about a third of the cases and prevention in the remainder, excepting less than 1 per cent who were unaffected. Approximately the same attenuation, with proportionate economy, was attained from half doses given before the sixth day. More work is required to ascertain the dosage most likely to produce attenuation. Attenuation has the advantage that, however mild and fleeting the attack of the disease, permanent immunity follows, whereas, if the disease is entirely prevented, the immunity lasts only a few weeks.

Sugars Made in the Laboratory

Addressing the British Association of Chemists, E C C Baly, professor of inorganic chemistry in the University of Liverpool, made the stupendous announcement that by the action of light, as in the living plant, he had produced sugars in the laboratory. The process consisted of two parts: the photochemical conversion of carbonic acid into what might be called active formaldehyde, and the polymerization of the formaldehyde into sugars. The proof of the formation of the sugars by photosynthesis in the laboratory was complete. This was achieved with nickel carbonate (which when irradiated by light was converted into nickelic oxide and active formaldehyde), a process exactly analogous to that of the living plant. Other workers had failed to confirm the successful results obtained at Liverpool, and this could be explained. If impurities were present in the first of the two stages effected by light, the substance produced reverted to carbonate as fast as it was formed. Photosynthesis had also been achieved by the irradiation of cobalt carbonate, and the proof of that phenomenon was free from any doubt. The two-stage theory of activation thus reached offered a satisfactory explanation of all the heretofore unexplained observations made with living plants.

The Indian Medical Service Endangered

The desire of the British government to give self government to India has encountered great difficulty in consequence of the action of Indian extremists, who, notwithstanding the benefits of British rule, are fanatically hostile to any British rights whatever. In a previous letter the desire to exclude British physicians from practicing in India was shown. Great concern is now felt for the greatest colonial medical service in the world, the Indian Medical Service, which not only introduced European medicine into India but founded medical schools there and played a great part in the creation of tropical medicine. The British Medical Association has prepared a memorandum for submission to the India Select Committee (which is working out the scheme of self government for India) expressing the view that disintegration of the Indian Medical Service is bound to follow the proposals made. It will cease to attract physicians of the highest attainment. The main contentions of the association are that 1 Successful recruitment of the service cannot be maintained if the civil branch of the service is discontinued (This refers to the fact many of the prizes of the service are civil medical appointments) 2 The scheme for employing

British physicians for contract service in the respective provincial medical services will not be useful. 3 Medical provision in India, including administration, teaching and public health, should include a due proportion of British personnel. 4 The women's medical service should be expanded and should include a due proportion of British medical women for teaching, administration and research. It is further pointed out that under the proposals a military reserve of British physicians would not be available in time of emergency or war, also that adequate medical attendance on British officers and their families by British physicians would not be insured.

Tubercle Bacilli in the London Milk Supply

An important report on the milk supply of London has been made to the central public health committee of the London county council. An entirely new position has arisen from the practice adopted in recent years of receiving country milk at depots, where it is bulked and transported to London in large glass-lined tanks, each holding about 3,000 gallons. As these tanks contain milk from many different herds, the addition of tuberculous milk from one farm infects the whole. The first examination of ten road and rail tanks showed that all contained living virulent tubercle bacilli. The results of the examination of London milk show that in the prewar period from 1907 there was a steady decline in samples found to be tuberculous from 11.6 to 7.9 per cent. In the earlier war period the percentage continued to fall but rose again in 1916 and attained a maximum about equal to that of the prewar period. Then it fell rapidly for a decade and reached the unprecedented low level of 2.6 in 1922. But since then it has risen steadily until now it is back nearly to its old figure: the percentage in 1932 being 9.3 for can milk and 10.9 for all samples, tank and can. About 40 per cent of London milk now arrives in tanks. The latest figures for tank milk (for the quarter ended March 31, 1933) show that, of forty-one samples, thirty-four, or 83 per cent, contained tubercle bacilli.

PASTEURIZATION

But these figures apply only to the milk on arrival in London. Practically all the tank milk comes to the big dairy firms, where it is pasteurized on arrival. An examination for the purpose of this special investigation of 282 samples purchased over the counter showed that nine, or 3.2 per cent, contained tubercle bacilli. These samples included milk sent to London both in tanks and in cans and the presumption is that those containing tubercle bacilli had not been pasteurized, at least not effectively. It is now believed that 90 per cent of the milk supply of London is pasteurized. While there is no reason to believe that commercial pasteurization is not, in the hands of many firms, equivalent to pasteurization as required by the ministry of health, the process is uncontrolled to the extent that no public authority gives a guaranty, as it does in the case of milk sold as 'pasteurized,' that the plant has been inspected and approved.

The committee recommended that copies of the report be forwarded to the minister of health and the minister of agriculture, that the appropriate minister should urge on the county councils concerned the great importance of insuring a milk supply free from tubercle bacilli and other contaminating organisms and that the ministers be asked to consider what action should be taken, or further powers obtained, in order to overcome the difficulties created by modern methods of milk transport.

The Problem of Mental Defectives

Lecturing at the London School of Hygiene and Tropical Medicine Dr Cyril Burt, professor of psychology at University College London, said that on the main question of sterilization every one was agreed. But he did not think that it would do much to solve the problem of the mental defective. How many children in the London schools for defective children

had defective parents? The majority were from temperamentally unstable or dull parents. If an attempt was made to sterilize all the "carriers" of mental deficiency, about a fifth of the population would have to be sterilized. That would be ludicrous. No single remedy would be sufficient to deal with the whole of the problem. Professor Burt advocated mental inspection in addition to the present medical inspection of school children. What was wanted was a population of mind power rather than man power. A real survey of the whole population was needed. Mental deficiency was actually on the increase in rural areas, which had a larger proportion of defectives than the towns. Lured by the attractions of the cities, people had been flocking into them in the last fifty or sixty years, leaving all the dull yokels behind. There they had remained, and inbreeding no doubt aggravated the dullness. In Warwickshire, where Shakespeare came from, it had been found that nearly 4 per cent of the rural population of the county were mental defectives. In the village from which Shakespeare emerged, three surnames accounted for 70 per cent of the population which showed the enormous extent of inbreeding.

The Examination of Automobile Drivers

A convention was held in Paris, during the annual automobile show, to consider the problems affecting the "safety of the highways." In addition to discussions about automobile brakes, modes of illumination, signals and road signs, an entire session was devoted to discussing the medical examination of drivers of automobiles. Numerous accidents are, no doubt, due to the bad physical condition of the drivers manifested in such ways as poor vision or hearing, dizziness due to circulatory disorders, epilepsy, nervous disorders or alcoholism. As far back as 1923, the Academy of Medicine demanded that persons affected with serious organic defects be not permitted to drive an automobile. That resolution had no direct effect. Mr. Andre Tardieu, during the period that he served as minister of public works, was asked, in 1927, on the floor of parliament, by a member of the chamber of deputies, whether it was not possible to require a medical certificate attesting to the competence of every person who drives an automobile. At that time there were more than 300,000 automobile drivers, and Mr. Tardieu said that such an examination, although desirable, was practically impossible. He emphasized that if the requirement should be made retroactive it would take several years and necessitate the mobilization of more competent experts than the country could furnish. It was decided therefore to subject to examination only such persons as became involved in automobile accidents, the purpose being to discover whether they were suffering from any physical defect that would render their driving dangerous. The permit to drive was withdrawn from persons who had driven while in a state of intoxication, as established by the decree of 1928. In June, 1930, the Academy of Medicine renewed its demands. Acting on a report of Dr. Claude, it demanded that every automobilist on whom any penalty whatever is imposed, even though only because of having exceeded the speed limit, be required to submit to a mental examination.

As of Aug. 1, 1930 the minister of public works who has charge of everything pertaining to the highways, decided that a medical examination should be required of all persons requesting a permit to drive large public vehicles. The examination to be given by one or a group of physicians designated by the prefect of the department. In 1931 the Academy of Medicine requested that this examination be construed to include drivers of all vehicles carrying more than eight persons and

that it be renewed every two years for public corporations and every year for private enterprises. In Paris, the prefecture of police imposes a rigorous examination on all drivers of autobuses, the certificate based on such examination being subject to renewal periodically. The results have been excellent, for the Paris autobus company, since the introduction of these regulations, has observed that accidents caused by its vehicles have diminished by 16 per cent and that, in indemnities paid to victims, it has saved 1,500,000 francs (\$90,000). The drivers of taxis have not yet been made subject to this examination, but demands are heard on all sides that the examination should include them. Of thirty-six taxicab drivers subjected to an examination by Dr Toulouse, at the Psychiatric Institute of the Hôpital Ste Anne, after having become involved in accidents, ten were found to be affected with dementia paralytica, twelve with psychasthenia associated with impulses and obsessions, two with alcoholic dementia, two with epilepsy, two with toxicomania, four with alcoholism, and three with dementia praecox.

The convention on the Safety of the Highways heard Dr Levy-Valensi report all these facts. He referred to the research of Professor Tanon, who has shown that attacks of vertigo may be observed, on the highways, in drivers who have gradually been overcome by exhaust gases in closed automobiles, these gases filtering in through the cracks in the floor of the car, and who has pointed out also that previous ingestion of alcoholic beverages makes a driver more sensitive to this type of intoxication. He emphasized the necessity of eliminating persons with but one good eye, as is done in Belgium. Mr Levy-Valensi concludes that the following classes should be refused permits to drive: (1) persons affected with progressive diseases of the nervous system, and those whose permanent lesions are incompatible, even after correction with an apparatus, with the proper management of an automobile; (2) persons subject to attacks of hysteria; (3) all epileptics; (4) all psychopaths, with the exception of a few "intermittents," who should be subjected to frequent examination, if they are allowed to drive; and (5) chronic alcohol addicts, who are subject to repeated attacks of drunkenness—to which the convention added heart patients and persons subject to attacks of angina pectoris. It was proposed that permission to drive be refused to applicants more than 50 years of age, for after that age one cannot count on a good training of the reflexes. The convention, at which automobile manufacturers and their representatives predominated, took a peculiar attitude toward the discussions. It was apparent that the convention was not favorable, on the whole, to any restrictions that would be likely to diminish the number of automobile buyers. The majority of the persons present objected to nearly all the measures proposed on the subject by Dr Levy-Valensi, Dr Godlewski and Dr Balthazar. It rejected in a formal manner the imposition of periodic examinations on drivers of other than trucks and large public autobuses. It favored a psychotechnic and medical selection only for professional drivers and a periodic revision of the administrative list of defects constituting inaptitude. The daily press has been evasive on the subject. The medical writers of the political journals, who had prepared for the occasion a number of articles designed to enlighten the public on the subject, were unable to publish them, as they were rejected by the managers of the newspapers at the request of the syndicate of automobile manufacturers, who are big advertisers, for the reason that, in the present state of affairs, it was not desirable that anything should intervene, in the form of a medical examination, that would interfere with the sale of automobiles. The only hope on which one can base suitable control, so far as drivers of private cars is concerned, lies in the accident insurance companies, who are considering the possibility of requiring

a medical certificate of aptitude before approving an application for accident insurance. But even this hope is illusive, for all the accident insurance companies are fierce competitors of one another, and an understanding in this matter will be difficult to effect.

International Convention on Combating Tuberculosis

The annual session of the council of the Union internationale contre la tuberculose, the president of which is Professor Nolen of the Netherlands, was held in Paris, and fourteen countries were represented. A session of the council was held at the headquarters of the Union, 66 Boulevard St. Michel, in the forenoon. The scientific session was devoted to the presentation of a paper by Dr A. Saenz on "Tuberculous Bacillema." This paper was followed by a general discussion, in which Prof. Leon Bernard, general secretary of the Union, Professor Valtis of Greece, Professor Bezançon of Paris, Prof. Yevrem Nedelkovitch of Yugoslavia, and others participated. The next international conference will be held in Warsaw, Sept. 4-6, 1934, and the following topics have been placed on the agenda: "Biologic Variations in the Tuberculous Virus," Professor Karwacki, Poland; "The Types of Osteo-Articular Tuberculosis and Their Treatment," Professor Putti, Italy; and "The Use of Dispensaries for the Treatment of the Tuberculous," Prof. Leon Bernard, France. An address on the "Supplementary Measures in Combating Tuberculosis in a Rural District in Which the Mortality Rate is Low" will be delivered by Mr. John A. Kingsbury, United States. Following the precedent adopted at the convention held at Oslo and The Hague, ten speakers will be chosen from various countries for each topic, in addition to the principal speaker.

Alcoholism and Heredity

Addressing the Freiburg Medical Society, Professor Seiffert of the Freiburg Hygienic Institute reported a study of large groups of children (1,700 from the Kaiserstuhl region and 2,000 from the Margrave territory) as to whether alcohol has any hereditary influence on the gonads. These two regions are well known because of the wines produced there. Records were made with regard to height, weight, chest girth, constitutional type and qualities, and performance in the 60 meter dash. The figures obtained were compared with figures from other regions, as from Freiburg itself. It was found that the children from the grape-growing regions were better developed than the children constituting the control material. Seiffert draws the conclusion that alcohol has no practical importance from the standpoint of its hereditary influence on the gonads. Later, the genealogies of twenty heavy drinkers who were treated in sanatoriums were studied. It was ascertained that heavy drinkers who had no bad hereditary tendencies had healthy children from healthy wives but that with heavy drinkers who displayed such hereditary tendencies it was different. In the latter case, differences were manifest, the nature of the differences depending on whether the bad hereditary influence emanated from one or from both parents. If only from one parent, the research revealed that the effects on the children were not particularly marked, but if from both parents, from 30 to 60 per cent of the children were affected. The conclusion may be drawn that it should be made the rule to compel an alcohol addict to accept treatment on the basis of a physician's advice and not on the basis of a court decision, and that if there is evidence of a marked hereditary trend toward alcoholism the alcohol addict should have a guardian appointed. Heavy drinkers with a marked hereditary trend toward alcoholism, who

periodically become intoxicated, should not be placed in expensive sanatoriums but in a workhouse, where they can earn their living. To sterilize the heavy drinkers in a sanatorium would not help much, since they are usually advanced in years. The selection of addicts to be sterilized should be made from among those who are admitted to the department of public welfare. The problem of finding some means of reducing the number of persons with strong hereditary trends toward alcoholism is an urgent one.

New Trends in Demographic Science

Under the direction of the federal ministry for popular enlightenment, a vigorous publicity campaign on problems pertaining to hereditary biology has been planned. The purpose is to promote discussion of fundamental questions of demographic science: the declining birth rate, economic problems, the law on the prevention of offspring with bad hereditary tendencies, and questions concerning the preservation of the purity of the race in every way possible—through the press, the radio, and the like. It is planned to distribute millions of pamphlets dealing with the demographic policies of the new government. The ministry has appealed to all organizations, leagues and associations to work for the dissemination of these ideas. Detailed demands and proposals are made. The associations are urged to lower the dues of members who have large families. The directors of every association should see to it that every member of their organization becomes familiar with the official publicity material that has been distributed. The pamphlets distributed at a low cost by the local headquarters of the national-socialist party are calculated to bring in money with which to furnish practical aid to the heads of large families. All meetings of the associations and leagues during the next few months must be permeated with hereditobiologic ideas and plans.

The Cost of Health Insurance

As announced the cost of medical care of members of the associations of the federal health insurance system amounted in 1932 to a total of 258,536,000 marks (\$93,000,000, current exchange), as compared with 328,224,000 marks (\$118,000,000, current) in 1931. In other words, in 1932, 1514 marks (\$5.45), on an average was expended for each member, and in 1931, 1728 marks (\$6.22). Whereas the total expenditures for medical treatment have diminished by 21.2 per cent the cost per member as a result of the simultaneous decline in membership of 10.2 per cent due to the increased unemployment growing out of the economic crisis, shows only a decrease of 12.4 per cent. The expenditures per member in the metropolitan industrial regions amounted to 1605 marks (\$5.78), in the prevailingly industrial regions, to 1536 marks (\$5.53), in the predominantly agricultural regions to 1424 marks (\$5.13), and in the purely agricultural regions, to 1344 marks (\$4.84).

Combating Quackery in Danzig

The Free State Danzig has now a decree for the protection of public health. It provides that cancerous diseases, diseases of women and children transmissible and infectious diseases, and particularly venereal diseases and tuberculosis, may be treated only by licensed physicians. Irregular practitioners must present themselves to the district physician and prove their ability to recognize dangerous and infectious diseases. If they are unable to furnish satisfactory proof of such ability they will be required immediately to abandon their activities. Furthermore unlicensed practitioners are prohibited from performing any intervention associated with an injury of the tissues (injections, vaccination). They are likewise forbidden to use dangerous apparatus.

Schools for Persons with Impaired Vision

A convention of the Association internationale de prophylaxie de la cécité was held in Paris, Nov 19, 1932, under the chairmanship of Professor de Lapersonne. The entire session was devoted to a discussion of the school for persons with amblyopia. In Belgium nothing has been done in this field. Professor Weekers presented a comprehensive paper on the subject before the Société belge d'ophtalmologie. The first question considered was: What children attend a school for pupils with impaired vision? The regulations on this subject are of a tentative nature, since the institution of schools for the preservation of eyesight is of recent date. Nevertheless, certain rules are beginning to take shape. Notably Bartels regards as amblyopic all children whose vision is too good for them to be placed in institutions for the blind and too weak for the ordinary school, although sufficient to permit them to learn to read and write. The visual acuity ranges between 2/10 and 4/10, after correction. Myopic children affected with marked and progressive myopia may be admitted to these schools even though their visual acuity is in excess of the limit indicated. The same principle applies to disorders of the superficial or deep-lying ocular membranes with an evolutionary and progressive tendency.

THE NUMBER OF SCHOOLS NEEDED

Owing to the relatively small number of amblyopic children, the creation of a completely equipped school for amblyopic pupils is justified only in cities with at least 100,000 people. A certain number of amblyopic children of nearby rural districts will usually attend the city school. The others may be admitted to the best available school or may be given private instruction. Following the paper of Professor Weekers, the society adopted the following resolution: The Société belge d'ophtalmologie hereby expresses the desire that special schools for children with impaired vision be created in the field of primary education. These children are unable to attend ordinary schools, nor are they in their proper place in institutions for the blind. Their education and their whole life outlook suffer from the lack of such schools. The results secured in the schools for the preservation of eyesight, which have been functioning for several years in various countries (England, France, Germany, Switzerland and the United States), are excellent. It is the duty of our country to follow the general trend on pain of being left behind in matters of education.

Otorhinolaryngologic Congress

At the thirty-ninth congress of the Société belge d'oto-rhino-laryngologie, held at Ghent, under the chairmanship of Dr. Driesbeque, Van Caneghem reported on the pressure and the chemical and cytologic composition of the cerebrospinal fluid in thirty-four patients with extradural complications of ear infections. He found that in half the patients there is hypertension of the cerebrospinal fluid, and that in a third of the cases the hypertension is rather marked (more than 30 cm of water). This hypertension is noted especially in patients who present an extradural abscess, so that if, in a patient affected with mastoiditis, a pressure above 30 is observed it is likely that he presents an extradural abscess. Normal tension does not exclude the possibility of a like abscess. Hypertension does not aggravate the postoperative prognosis nor can it be explained by a collateral edema or by toxic phenomena but only by changes in the circulatory system. In four patients, chemical and cytologic changes in the cerebrospinal fluid were found in the absence of any meningeal phenomenon. They may constitute a first stage in the evolution

of ordinary meningitis, they do not constitute the clinical syndrome of serous meningitis

Bronchoscopy in Acute Lung Abscesses

Soulas of Paris pointed out that acute pulmonary abscesses in the adult are greatly benefited by intrabronchial treatment. If the patient is treated from the third or fourth week, a few sittings may suffice to effect a radical cure (in forty-seven patients the author secured thirty-three cures, as confirmed by the test of time from eight months to four years. In some cases, after a definite improvement is brought about, a surgical operation may be necessary (third or fourth, or even the fifth month), and its prognosis is then favorable. The bronchoscopic method does not consist in "broncho aspiration" or broncho-injection, it involves a much more complex intrabronchial action, the basis of which is a cleansing process or removal of bronchial obstructions, combined with simple instillations.

Society News

The annual congress of the Association of French-Speaking Physiologists was held at Liege, June 7-10, under the chairmanship of Professor Dubois, dean of the Faculté de médecine de Lille. Three papers, by J. Demoor, H. Cardot and V. Henri, and many other communications were presented.

BUCHAREST

(From Our Regular Correspondent)

Oct 13 1933

The Distribution of Narcotics Becomes a State Monopoly

The new health law contains a paragraph which says that henceforth narcotics will be imported and distributed only by the state. A minimal quantity to be purchased is prescribed by the law. In consequence of this order, the prices of proprietary medicines containing narcotics rose sharply. The ministry of health, seeing the detrimental action of the law, in its latest order repealed that part of the law relating to centralization of the distribution of narcotics. The Bucharest office will restrict its activity only to the imposition of the import duties, which were raised considerably. Importers will pay 10 per cent of the face value of all consignments. In pharmaceutical circles it is thought that the ministry of health has given up the idea of centralization of distribution. At the same time they express their indignation over the 10 per cent duty which they find exorbitant.

In another order, the ministry of health introduced a new stamp tax levied on all kinds of cosmetics. The minister intends to extend the tax to all kinds of proprietary medicines to protect the interests of dispensing chemists who complained to the ministry of health. Ten years ago they dispensed ten medical prescriptions to one proprietary medicine; at present the rate is just the reverse, they sell ten packages of proprietary medicines to one prescription brought to them for dispensing.

Balkan Medical Week

The Balkan Medical Week is held once a year in one of the Balkan states, namely, Yugoslavia, Rumania, Bulgaria, Turkey or Greece. This year it was held in Belgrade, September 11-13. The first congress was held in 1930 at Athens, the second in 1931 at Constantinople, the third in 1932 at Bucharest. At the Belgrade medical week, the Rumanian delegation was led by the official representative of the ministry of health, Dr. Deculescu, state secretary. The program consisted of discussions of the following themes: the role of physicians in the union of the Balkan people, hygienic problems of school children, health in the villages, housing conditions in the rural parts of the Balkan states, inter-Balkan public health collaboration, public health conventions between the Balkan coun-

tries, antituberculosis work, pediatrics, the malaria problem in the Balkan states.

The week was opened in the presence of medical delegates of Yugoslavia, Rumania, Bulgaria, Greece and Turkey, in the spacious and beautifully decorated hall of the Yugoslavian Medical Association. Professor Marcovici, president of the Yugoslavian committee, presided. Speeches were made by Deculescu, state secretary, Professor Topa, vice president of the Rumanian delegation, and Akil-Muktar Bey, dean of the medical faculty of Constantinople University.

The Belgrade physicians received their colleagues with the greatest cordiality. They arranged excursions, which offered interesting views; they demonstrated what a strong will, hand in hand with the monetary support of the Rockefeller Foundation can do and what improvement can be achieved within a single decade in the public health conditions of a country. The guests were given transportation at the frontier of Yugoslavia in Pullman cars, and delegates did not pay during the whole week for trains or for boat fares; they were regarded as the guests of the Yugoslav state.

Pellagra and Malaria in Jassy County

A few years ago there was a general boom among the farmers, and their living conditions were favorable. Pellagra was then almost extinct in Rumania, where a great part of the rural population is consuming maize bread, the flour used being blended with wheat flour. The economic crisis in recent years has forced agricultural laborers to make their bread from pure maize flour with the consequence that pellagra is common in the county of Jassy, the poorest district in Rumania. The ravages of pellagra were augmented by the meteorological conditions this year. The summer was exceedingly wet; rain poured in torrents almost continuously in June and July, so that maize could not ripen in due time. As the peasants needed it for food they cut it down when only half matured, and instead of bread they consumed maize. The magistrates enlightened the rural population about the dangerous consequences and in some places they sent out inspectors to prevent the cutting of raw and damp maize.

During the excessively rainy summer, many small streams and rivers inundated the adjacent areas. In Jassy County the river Moldava inundated almost all the meadows of the county, which thus became a nest of mosquitoes and malaria. According to the report of the county medical officer, there are more than 10,300 malaria patients in the county. In September, 3,306 fresh cases, with three deaths, were reported. The largest number of cases were in the villages of Stolniceni, between the Pruth and Jijia rivers where the malaria-free inhabitants could be counted on one's fingers, but in villages built on the slopes, where water could flow down freely, no malaria appeared. The health authorities distributed free quinine, mainly as pills containing 0.05 and 0.10 Gm.

The Protection of Mothers and Children

The text of a new plan for the protection of mothers and children has been sent by the ministry of public welfare to institutes and professional organizations. The intention of the minister being that in the final drafting of the law all those concerned should be satisfied. According to the plan as laid down in the draft, pregnant women, mothers in childbed, and children up to their eighteenth year are entitled to medical and social assistance. The new law will require that in the future couples to be married must undergo a medical examination and be granted a certificate by a city medical officer to be produced before the registrar. The new law contains three drastic paragraphs for controlling abortions.

The draft states that working women in the last two months of pregnancy shall be entitled to a holiday with a certain

fraction of their regular wages. Children up to their eighteenth year will be subject to health control, exercised by the parish or by the town physician in the homes of children and in schools, workshops, studios, factories or other such enterprises where persons under age are working. The ministry of public welfare deems necessary the erection of medico-social dispensaries and clinics for mothers and children, maintained partly by the state and partly by the municipalities.

The Destitute Children in Russia

Dr Leo Constantinescu, who has returned from Russia after a sojourn of sixteen years, having been taken prisoner in 1917, gave a popular lecture on the destitute children of Russia. He said that during the rule of the czars there were many children whose parents fell in the war or who became separated from their parents during the flight before invading soldiers. The wretched years succeeding the World War are responsible for the almost countless number of destitute children who wander about in the vast area of the soviet domain. Hundreds of thousands of starving children, the so-called *Besprisonnys*, are tramping all over the country begging, starving, stealing and indulging in cocaine and sex vices. They roam in large groups from town to town, with a predilection for the railroad tracks, and sometimes their begging assumes a rather threatening character. They have no abode but spend the night under bridges or in tunnels and sheds and naturally become ruined physically and morally. The Russian magistrates realize this danger but have failed as yet to relieve the situation.

CAPE TOWN

(From Our Regular Correspondent)

Oct 10, 1933

Annual Meeting of Medical Association

The Annual Scientific Meeting of the Medical Association of South Africa, popularly known as the Medical Congress, was opened by Vice Admiral Evans, commander of the African station, September 25, and lasted for six days. The president of the congress this year is Dr E. B. Fuller, a specialist in urology and one of the founders of our first medical faculty at the local university. The congress was held in the university buildings, the gardens of which are a blaze of color, owing to the massing of veld shrubs and annuals. It was attended by about a fifth of all practicing physicians, an unusually high attendance. The program was well arranged but, as usual on such occasions, rather overloaded so that there was little time to discuss adequately the various papers. One of the most interesting discussions was at the combined session of the medicine and public health sections, which had invited the veterinarians to attend to debate the question of bovine tuberculosis. The discussion was opened by Dr Gilles de Kock of Onderstepoort, the fine experimental and research veterinary laboratory near Pretoria established many years ago by Sir Arnold Theiler. Dr de Kock emphasized the close connection between human and animal diseases and pleaded for the more general recognition at medical congresses of comparative medicine, a plea originally made by Sir Clifford Allbutt that has heretofore fallen on unsympathetic ears. The discussion stressed the importance of bovine tuberculosis as a factor in the general incidence of tuberculosis, a disease that is rapidly spreading in this country. The meeting passed a resolution calling on the government to initiate an investigation into the incidence of bovine tuberculosis. Reference was made to the present unfortunate method whereby natives contracting tuberculosis in the towns were permitted to return to their kraals, where they were not under supervision and were likely to spread the disease.

Another interesting session was devoted to the discussion of medico-legal subjects in general practice. This was opened by

Dr C. J. Albertyn of Pietermaritzburg, who insisted on the urgent necessity to educate district surgeons and general practitioners in country areas in modern forensic medicine. The government has lately consented to join forces with the University of the Witwatersrand and to appoint three whole time district surgeons, who would at the same time act as lecturers in forensic medicine at the university. This is a step in the right direction, for so far there has been no recognized medico-legal expert in the country, and the judges have more than once commented on the unsatisfactory manner in which medico-legal evidence has sometimes been submitted to the courts. A resolution was passed calling on the government to provide similar facilities to those granted to the Witwatersrand and the University of Cape Town, which is the older medical faculty.

The Medical Council

The charter of the profession is the medical, dental and pharmacy act of 1928, which stipulates that there shall be a medical council, of which ten members shall be elected by the profession by ballot. The term of office of the council expires this year, and the retiring president, Dr Davies, has just issued a report of what the council has done during its term of existence. It has drawn up a code of rules, settled several disciplinary cases, and advised the government on matters in which the profession is intimately concerned. The government nominees on the new council have already been appointed. They include Dr Davies, who was an elected representative in the last council, and Dr Stals. The nominations for the elected representatives are not yet known but it may be taken for granted that they will consist of members of the medical association and, for the most part, specialists. It is generally considered that it would be a good thing if the council had a fair sprinkling of general practitioners among its members. The chief difficulty in securing this is the enforced absence from private practice inseparable from attendance at council meetings. Nevertheless, efforts are being made to induce general practitioners to stand for nomination. At the last election the association ran a "ticket" and was successful in getting most of its nominees appointed, but that method was criticized and this year it has been decided that each province is to nominate six candidates and that the whole twenty-four so nominated shall be balloted for. The act stipulates that not more than four members of the council shall be resident in one province, so that this list of twenty-four candidates ensures a free and fairly wide choice.

The Association's Gold Medal

The medical association awards a gold medal for "meritorious services rendered to the profession." The first medal was awarded two years ago to the veteran Dr Darley Hartley, emeritus editor of the association journal. The second medal has been awarded to Dr J. A. Orenstein, director of sanitation of the Rand mines, who for six years held office as president of the association and was largely responsible for the amalgamation of the two medical associations in this country into the present strong association. Dr Orenstein is lecturer on tropical medicine to the University of the Witwatersrand, which bestowed the honorary degree of LL.D. on him two years ago. He assisted Colonel Gorgas in Panama and was a co-author with Dr Prince of the history of the medical administration of the Canal Zone.

Report of Carnegie Commission on Poor Whites

The Carnegie commission on the poor white problem has finished three years work and has published a voluminous report, really a series of reports. The medical and hygienic aspect of the problem has been studied by Dr Murray, one of the assistant health officers of the department of public health.

of the union. He finds that there is no evidence to show that climate, humidity or excessive sunlight leads to physical deterioration and, contrary to most other observers, he is not convinced that malaria plays any important part in the production of poor whites. His data on the latter point, however, are far from conclusive and tend to show merely that in the small groups that he studied the physical effects of malaria could be regarded as negligible. He is of opinion that malnutrition, largely due to insufficient and badly prepared food, is a considerable factor in retardation. The other reports deal with the economic and educational aspects of the problem. The most interesting of them is that which relates the results of the study of intelligence among poor white children and their response to various mental tests, some of which have been specially standardized for children born in South Africa.

Marriages

EDWARD M. DE YOUNG, Nashville, Tenn., to Miss Alma Idell Jackson of Douglas, Ga., at Grand Rapids, Mich., August 28.

JAMES HENRY BOLES, Charleston, W. Va., to Miss Catherine Grace Rupert of Rochester, N. Y., October 18.

GEORGE W. BARTELS, Janesville, Wis., to Miss Winifred Virginia Kyler of Cedar Falls, Iowa, September 16.

FORREST L. CARPENTER, Latta, S. C., to Mrs. Margaret Gailhard Bethea at Monroe, N. C., September 20.

LAWRENCE IGNATIUS CLARK, Toledo, Ohio, to Miss Mae Reardon of North Scituate, Mass., September 27.

GIVEN JACKSON BRIDGES, Atlanta, Ga., to Miss Margaret Eugenia Raymond of Augusta, September 21.

ROBERT H. BELL, Carlinville, Ill., to Miss Lydia Reichmann of St. Louis at Indianapolis, September 5.

WILLIAM C. BERNSTEIN, New Richland, Minn., to Miss Mildred Goldberg of Minneapolis, recently.

ROBERT CLARKE, JR., Grant City, N. Y., to Mrs. Elizabeth F. Gallagher of New Brighton, October 15.

PAUL LAWRENCE DENT, Quinwood, W. Va., to Miss Willhda Hall Rickman of Roseland, Va., recently.

WILLIAM JAMES CUSICK, Elmira, N. Y., to Miss Doris Romana Conboy of Geneva, October 18.

CHARLES HALL ASHFORD to Miss Caroline Winder Dunn, both of New Bern, N. C., October 28.

CHARLES MEADOWS CLARK to Miss Evelyn Howard, both of McMinnville, Tenn., October 27.

ALLEN STEINWEHR AVERY to Miss Margaret Crawford, both of Toledo, Ohio, October 27.

SAMUEL CLARK FAIR to Miss Virginia Manson Hunt, both of Memphis, Tenn., September 22.

GILRUTH DARPINGTON, Yazoo City, Miss., to Miss Anne Du Buisson Hogue, October 6.

GEORGE LAMAR ARRINGTON to Miss Mary Wilbourn, both of Meridian, Miss., October 7.

HUBERT H. BLANCHARD, Milwaukee, to Miss Sara M. Cox at Waycross, Ga., October 11.

WILLIAM WARD BAXLEY, Porterdale, Ga., to Miss Stella Cater of Macon, November 4.

ABBOTT WILLIAM ALLEN to Miss Helen E. Coughlan, both of New York, September 9.

AUBREY C. BENJAMIN to Mrs. Frances A. Eddy, both of Chelsea, Mass., in October.

HARLEY C. CRANE to Miss Marian Jean Martin, both of Flint, Mich., September 2.

ZENAS HORACE ELLIS, New York, to Mrs. Mignonette Hills at Reno, Nev., August 7.

HENRY ROOSEVELT CRAIG to Miss Anne Rosamond Oliver, both of Detroit, July 8.

JOHN C. DRAKE to Miss Ruth O. Firestone, both of Indianapolis, September 15.

WILLIAM G. BANDY to Miss Eunice Jones, both of Lincoln, N. C., in August.

Deaths

BURTON JAMES LEE of New York, Columbia University College of Physicians and Surgeons, New York, 1898, professor of clinical surgery, Cornell University Medical College, member of the American Surgical Association, the Society of Clinical Surgery and the Radiological Society of North America, member and past president of the American Radium Society, formerly secretary of the American Society for the Control of Cancer, fellow and at one time member of the board of governors of the American College of Surgeons, clinical director and attending surgeon to the Memorial Hospital, associate attending surgeon to the New York Hospital, consulting surgeon to the Sharon (Conn.) Hospital and the Elizabeth A. Horton Memorial Hospital, Middletown, N. Y., served during the World War, was decorated with the American distinguished service medal and the French *croix de guerre*, author of several monographs on cancer and tumor of the breast, contributor of articles to *Keen's Surgery* and the *Oxford Loose-Leaf Surgery*, aged 59, died, November 12, of coronary thrombosis.

HUGH WARREN BRENT, Phoenix, Md., University of Maryland School of Medicine, Baltimore, 1903, member of the Medical and Chirurgical Faculty of Maryland, fellow of the American College of Surgeons, professor of clinical gynecology at his alma mater, served during the World War, formerly visiting gynecologist to St. Joseph's and University hospitals and Hospital for Women of Maryland, Baltimore, on the staff of the Union Memorial Hospital, Baltimore, consulting surgeon to the Annapolis (Md.) Emergency Hospital and the Edward W. McCready Memorial Hospital, Crisfield, aged 52, died, August 19, of a self-inflicted bullet wound.

WILLIAM FULLER, Chicago, Rush Medical College, Chicago, 1887, member of the Illinois State Medical Association, formerly professor of operative surgery and associate professor of clinical surgery at the University of Illinois College of Medicine, fellow of the American College of Surgeons, served during the World War, on the staffs of the Washington Park, Woodlawn and Englewood hospitals, aged 69, died, October 25, of uremia and carcinoma of the prostate.

GEORGE PULLEN PEED of Colonel, M. C., U. S. Army, Fort Slocum, N. Y., University of Virginia Department of Medicine, Charlottesville, 1895, veteran of the Spanish-American and World wars, entered the regular army as an assistant surgeon in July, 1903, and in December, 1903, was made a captain in the medical corps, was promoted through the various grades to that of colonel in 1929, fellow of the American College of Surgeons, aged 58, died, October 20, of heart disease.

GEORGE JOSEPH ECKEL of Buffalo, University of Buffalo School of Medicine, 1907, associate professor of medicine at his alma mater, fellow of the American College of Physicians, past president and secretary of the Buffalo Academy of Medicine, served during the World War, on the staffs of the Emergency Hospital of the Sisters of Charity, Buffalo City Hospital, Buffalo General Hospital and the Mercy Hospital, aged 55, died, October 29, of hypertensive heart disease.

LEWIS AUGUSTUS COFFIN, New York, University of the City of New York Medical Department, 1886, an Affiliate Fellow of the American Medical Association, member of the American Laryngological Association and the American Laryngological, Rhinological and Otolological Society, fellow of the American College of Surgeons, formerly on the staff of the Manhattan Eye, Ear and Throat Hospital, aged 77, died, October 30.

WILLIAM M. LESTER, State Park, S. C., University of Maryland School of Medicine, Baltimore, 1887, member of the South Carolina Medical Association, formerly member of the state board of health, on the staff of the South Carolina Sanatorium, aged 69, died, October 16, in the Memorial Hospital, New York, of esophageal diverticulum and epidermoid carcinoma of the base of the tongue.

WILLIAM THOMAS JOYNER of Roswell, N. M., University of Arkansas School of Medicine, Little Rock, 1889, past president of the New Mexico Medical Society and the Chaves County Medical Society, past president and secretary of the New Mexico Board of Medical Examiners, on the staff of St. Mary's Hospital, aged 66, died, October 12, of pneumonia.

CHARLES EDWARD WAITS of Atlanta, Ga., Atlanta Medical College, 1915, assistant professor of clinical surgery at his alma mater, past president of the Fulton County Medical Society, fellow of the American College of Surgeons, served

during the World War, visiting surgeon to the Grady Hospital and the University Hospital, aged 44 died, October 21

Lyman Asa Jones, Walpole, Mass., Harvard University Medical School, Boston, 1891, member of the Massachusetts Medical Society, at one time state inspector of health in the Berkshire District, formerly superintendent of the Pondville Hospital, Wrentham, aged 67, died, October 26, in the Norwood (Mass.) Hospital, of heart disease and hypertension

Wallace Leslie Britt ♂ Jackson, Miss., Atlanta College of Physicians and Surgeons, 1902, fellow of the American College of Surgeons served during the World War, on the staffs of the Mississippi State Charity Hospital and the Jackson Infirmary, aged 61, died, October 19, of injuries received in an automobile accident

Alvin Josiah Kern ♂ Slatington, Pa., Cleveland College of Physicians and Surgeons Medical Department of Ohio Wesleyan University, 1887, University of Pennsylvania School of Medicine, Philadelphia, 1888, formerly member of the state legislature for nine years member of the school board, aged 68, died October 14, of heart disease

Maurice George Albert Milan, Aberdeen, S. D., Georgetown University School of Medicine, Washington, D. C., 1913, member of the South Dakota State Medical Association, formerly on the staff of the Aberdeen Good Samaritan Hospital, aged 46, died, September 13, of influenza and pneumonia

Dale L. Martin, Tacoma, Wash., Northwestern University Medical School, Chicago 1909, member of the Washington State Medical Association, served during the World War, on the staff of the Tacoma General Hospital, aged 47, died October 14, in a hospital at Rochester, Minn.

Joel Crawford, Yale, Va., University of Pennsylvania School of Medicine, Philadelphia, 1883, member of the Medical Society of Virginia, past president of the Post Graduate Medical Society of Southern Virginia, aged 72, died, October 14, in the Petersburg (Va.) Hospital

Nelson Caryl Davis, Bahia, Brazil, S. A., University of California Medical School, San Francisco, 1921, member of the American Association of Pathologists and Bacteriologists, director of the Rockefeller Research Laboratories, aged 41, died, October 20

James M. Billings, Lebanon, Mo., Miami Medical College, Cincinnati, 1873, member of the Missouri State Medical Association, president and formerly secretary of the Laclede County Medical Society, county health officer, aged 89, died, August 28

Fred Rolland Dolson, Nowata, Okla., Tulane University of Louisiana Medical Department, New Orleans, 1898, member of the Oklahoma State Medical Association, veteran of the Spanish American and World wars, aged 59, was found dead, October 10

Norman Willis Johnson, Quasqueton Iowa, Keokuk (Iowa) Medical College, 1904, member of the Iowa State Medical Society, president of the Buchanan County Medical Society, served during the World War, aged 60, died, October 15

Sarah Lee Goodwin, Chicago, Hahnemann Medical College and Hospital, Chicago, 1893, aged 77, died, October 21, in the Ravenswood Hospital, of cardiac decompensation, following a fracture of the femur as the result of a fall

William Joseph McCrann, Papillon, Neb., Louisville (Ky.) Medical College, 1883, member of the Nebraska State Medical Association formerly on the staff of St. Catherine's Hospital, aged 78, died, October 13 of pneumonia

Cav Andrea De Lucis, San Francisco, Royal University of Turin Faculty of Medicine and Surgery, Italy, 1881, member of the California Medical Association aged 82, died, August 2, of aortic stenosis and coronary sclerosis

John Cunningham Maxwell, Sterling, Ill., College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1901 aged 67, died suddenly, October 14 in Houston, Texas, of cerebral hemorrhage

John William Sharpe, Toledo, Ohio, Faculty of Medicine of Trinity College Toronto, Ont., Canada 1878 University of Toronto Faculty of Medicine 1879, aged 73 died October 25, of myocarditis coronary sclerosis and influenza

Matthias Ambrose Wagner ♂ Toledo, Ohio, St. Louis University School of Medicine 1912, served during the World War aged 44 on the staff of St. Vincent's Hospital, where he died October 30 of duodenal ulcer

William Alexander Sloane Geddes ♂ Birmingham Ala., University of Toronto Faculty of Medicine, Toronto Ont.,

Canada, 1918, aged 44, died, October 23, in a hospital at Denver, of intracranial hemorrhage

John E. Baugh, Elkton Tenn., University of Louisville (Ky.) School of Medicine, 1880, bank president, chairman of the county board of education for twenty-five years, aged 74, died, October 29

Herbert Henry Williams, Mohawk, N. Y., Baltimore Medical College, 1911, member of the Medical Society of the State of New York, served during the World War, aged 50, died, October 15

John Wesley Clemmer, Columbus, Ohio Pulte Medical College, Cincinnati, 1876, formerly member of the city board of health aged 84, died, October 21, of cerebral embolus and cardiac disease

Oscar Porter Harris ♂ Mendota, Ill., Rush Medical College, Chicago, 1902, physician and owner of a hospital bearing his name, aged 62, died suddenly, October 29, of cerebral hemorrhage

Edwin Isaac Becker, Philadelphia, Jefferson Medical College of Philadelphia, 1897, on the staffs of the Jewish and Germantown hospitals, aged 55, died, October 29, of coronary thrombosis

John Daniel Doyle, Brooklyn, Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1898 on the staff of the Shore Road Hospital, aged 60, died, November 2, of pneumonia

Chester Grant Savage, Westerly, R. I., Baltimore University School of Medicine, 1898, member of the Rhode Island Medical Society, aged 64, died, October 12, of heart disease

Samuel Alpert, Chicago, University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1933, aged 26, intern at St. Joseph's Hospital, where he died, November 2, of brain tumor

Ira Tyson Clemons, Comanche, Texas Tulane University of Louisiana Medical Department, 1897, aged 63, died October 22, of injuries received when struck by an automobile

Samuel John Hartmere ♂ Boston, Tufts College Medical School, 1929 formerly on the staff of the Boston City Hospital, aged 38, died, November 1, of heart disease

William Shakespeare Taylor, Johnson City Tenn., Vanderbilt University School of Medicine Nashville, 1896, aged 61, died, October 16, in a hospital at Knoxville

Herman Richard Gundermann ♂ Monango, N. D., St. Louis College of Physicians and Surgeons, 1887, aged 70, died, August 4, in Edgeley, of embolism

John Harvey Gardner, New York, University of the City of New York Medical Department, 1879, aged 77, died, October 27, in Islip N. Y. of arteriosclerosis

George Clarke Webb, Federalsburg Md., Maryland Medical College, Baltimore, 1912, aged 50, died, October 19, of arteriosclerosis and cerebral hemorrhage

Julian E. Camp ♂ Augusta Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1880, aged 75, died, October 30, in Monmouth, of myocarditis

Charles L. Allen, Muncy Pa., Jefferson Medical College of Philadelphia, 1880, aged 75, died, September 19, of arteriosclerosis and angina pectoris

Charles A. Doolittle, Atchison Kan., Kansas City College of Medicine and Surgery, 1916, aged 65, died, October 22, of cerebral hemorrhage

Dareall Grant Black ♂ Wilkesburg Pa., Western Pennsylvania Medical College, Pittsburgh, 1899, aged 69, died, October 14, in Pittsburgh

John Joseph Gaynor, San Francisco, College of Physicians and Surgeons Buffalo, 1881, aged 79, died, October 5, of cerebral hemorrhage

Aaron Levine ♂ Cincinnati, Emory University School of Medicine, Atlanta 1926, aged 39, was found dead, November 1, of cerebral hemorrhage

James William Reid, Windsor, N. S. Canada Halifax (N. S.) Medical College, 1884, aged 74, died October 29, of heart disease

Samuel E. Gibbs, New York, Denver College of Medicine 1883 aged 90, died, September 25, of endarteritis and hypertension

Robert A. Moore, Silver City, Iowa, College of Physicians and Surgeons, Keokuk 1881, aged 79, died, October 9 of senility

William H. Langston ♂ Orlando Fla., Missouri Medical College, St. Louis, 1893 aged 63, died, October 17, of coronary embolus

Correspondence

THE FOURTH VENEREAL DISEASE

To the Editor—In the interests of uniform medical nomenclature and to avoid confusion in medical literature, I wish to call attention to the misapplication of the expression "the fourth venereal disease" as used by Cole in his otherwise excellent special article in *THE JOURNAL*, September 30. In this article the expression is used synonymously with "lymphogranuloma inguinale" in the title, while in the text the expression is used but once, when he says, "It has also been given such names as 'the fourth venereal disease,' 'tropical bubo,' " No reference is given as to when it was first spoken of as "the fourth venereal disease," but judging by the context I would assume that it was not many years ago. Neither was mention made of the disease "erosive and gangrenous balanitis," to which Corbus and Harris (*THE JOURNAL*, May 8, 1909, p 1474) gave the status of a fourth venereal disease, although previously Bataille and Berda (*Compt rend Soc de biol* 41 689, 1889; *Med mod* 2 340, 1891, cited by Young Practice of Urology 2 195, 1926) asserted that it always followed venereal exposure.

Lack of mention of the last named disease is probably due to its having escaped Dr Cole's attention and perhaps explains the misuse of the name in connection with "lymphogranuloma inguinale," a disease to which exudative and gangrenous balanitis has no apparent relation. This is no criticism of Dr Cole, as many urologists are unacquainted with the latter condition and in several textbooks on urology it is not even mentioned. Cabot's "Modern Urology," Volume 1, contains an excellent description of this disease by Corbus. Briefly it is an acute specific ulcerative and at times gangrenous balanoposthitis, apparently due to a spirillum and fusiform bacillus living in symbiosis, and further characterized by moderate inguinal lymphadenopathy and constitutional symptoms such as accompany almost any fever.

W M DONOVAN, M D, Scranton, Pa

[The letter was referred to Dr H N Cole, who replies.]

To the Editor—In reply to the note of Dr Donovan, I would say that I appreciate his calling my attention to the fact that erosive and gangrenous balanitis has been spoken of as the fourth venereal disease, in fact, I have already used this term, I am afraid, with my students in the past. It seems to me, however, that erosive and gangrenous balanitis will never assume the prominent position that lymphogranuloma inguinale has already taken.

In the first place, the average case of erosive and gangrenous balanitis is comparatively benign, if a correct diagnosis is made and if the proper type of measures is used, including the use of oxidizing agents, for example, potassium permanganate or hydrogen peroxide and, exposing the infected area to the open air.

Moreover, erosive and gangrenous balanitis is a far rarer disease than is lymphogranuloma inguinale, and finally the prognosis of an erosive and gangrenous balanitis is far better than what one may get in the average run of lymphogranuloma inguinale. It is rare indeed that one sees severe results from erosive and gangrenous balanitis. I can remember only two cases of mine in which a portion of the penis was destroyed, while with lymphogranuloma inguinale it is my opinion that any case is a potential matter of great importance, and even with the best of care the physician is taking care of a condition in lymphogranuloma inguinale that may lead to very serious end-results, because of the fact that no specific for the disease is available.

On that account I have used the term "fourth venereal disease" for lymphogranuloma inguinale, believing that it has far greater importance than does erosive and gangrenous balanitis, though it is true that the latter disease has in the past been termed "fourth venereal disease." I do not think, however, that this term was used any earlier for erosive and gangrenous balanitis than it has been for lymphogranuloma inguinale.

H N COLE, M D, Cleveland.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TREATMENT OF EXCESSIVE GROWTH AND OBESITY

To the Editor—I would appreciate your opinion and advice regarding the diagnosis and treatment of a case of obesity which strikes me as being mainly a glandular imbalance although there is probably some hereditary factor involved. A girl aged 8 years weighs 104½ pounds (47.5 kg) and is 55¼ inches (140 cm) tall. The hair of the scalp is abundant and of normal texture. The vision is 20/20 in each eye. The nose and ears are normal. The teeth are normal except that they erupted a little early for the patient's age. The throat is normal. The thyroid is not palpable. The chest heart and lungs are normal. The abdomen is normal except for three horizontal folds of fat extending across the abdomen the first at the upper part of the abdomen, another at about the middle and the third across the lower part. Her appetite is normal she eats little bread or potatoes. The gastro-intestinal tract is normal. The genito-urinary tract is normal except for well developed rather prominent mammary glands. The reflexes are normal. The mental development is normal for the patient's age, or perhaps a little above the average. The patient has the following measurements: head circumference 20¼ inches (51 cm), neck 12½ inches (31.5 cm), chest 30¼ inches (77 cm) just above the nipple line, abdomen at the umbilicus 30½ inches (77 cm), arm circumference 10 inches (25.4 cm), midway between the shoulder and the elbow wrist circumference, 6½ inches (16.5 cm). The fingers are short fat and moderately tapering. The knee circumference is 13½ inches (34 cm), the ankle circumference 8½ inches (21.5 cm). The length of the feet from heel to toe is 8¼ inches (22 cm). The distance from knee to heel is 15¼ inches (39 cm). The circumference of the hips is 32¾ inches (82.5 cm). The mother is living at the age of 46. She weighs 213 pounds (96.6 kg) and is 68 inches (173 cm) tall. The father is living at the age of 50. He weighs 18½ pounds (84 kg) and is 73 inches (185 cm) tall. There are three sisters aged 4, 15 and 17 years two are of average weight and one is slightly under the average. There are two brothers aged 11 and 13 years one is of average weight and the other is about 10 pounds (4.5 kg) underweight. Please omit name.

M D West Virginia.

ANSWER—From the description, this patient may be showing the effects of hyperactivity of the pituitary gland in regard to the growth hormone. The child is tall for her age and is greatly overweight even in relation to her height. Whatever the cause, however, the actual obesity is due to hyperalimination and can be reduced by dieting.

The calory requirement of the patient based on her ideal weight (73 pounds, or 33 Kg), is about 2,640 calories. A diet of 1,500 calories is sufficient for her basal requirement and growth and should cause her to draw on her fat stores for the energy expended in activity.

The following diet is suggested

Protein	100 grams =	400 calories
Fat	50 grams =	450 calories
Carbohydrate	160 grams =	640 calories

1,490 calories

Since the patient will draw largely on her fat stores for the calories not supplied in the diet, the fat content of the diet is about as low as is compatible with palatability. For this reason the carbohydrate content must be kept relatively high, in order to avoid acidosis. The protein content is high in order to insure proper tissue repair and because of its specific dynamic action.

In all such restricted diets special attention should be paid to the roughage, mineral and vitamin content. Because of the low fat content of the diet, it is wise to give the fat-soluble vitamins in concentrated form.

Any increase in muscular activity which the child can be induced to make especially in the form of play will of course aid in the treatment.

MICRO ANALYSIS OF BLOOD BY GRAVIMETRIC METHOD

To the Editor—I am interested in the micro analysis of blood by the gravimetric method. I have Bang's original work on this subject (1913) but nothing later. By now I should think a complete technic should be developed for this work. Has the Association any standard approved or official method for such determinations? If so how could I obtain such directions? If not could you give me any leads through which I could obtain the information I need?

RICHARD J. DEGRAI, Bethlehem, Pa.

ANSWER—The later development of Bang's micromethods for blood chemistry by the gravimetric method may be found in the textbook of Bang and Blum, *Mikromethoden zur Blutuntersuchung* Munich, Bergmann, 1927. The technic, in brief, is as follows:

The material under investigation is weighed instead of measured with a capillary pipet. The usual titration is used for further steps. In order to weigh such small quantities of fluid for analysis (from 0.1 to 0.15 cc.) Bang uses the torsion scale of Hartman and Braun (Frankfort-on-Main) which records the weight of the small quantity of fluid in a few seconds on a dial. A few drops of the fluid under investigation is placed on special filter paper weighing about 50 mg. (The proper quality of paper, already weighed, may be obtained from Emil Jensen A. G. Copenhagen, Warmbrunn and Qulitz, Berlin, or Hartman and Braun, Frankfort-on-Main.) The paper with the specimen is suspended as soon as possible on the torsion scale and the weight read immediately on a dial. The difference in weight between the empty sheet and that with the fluid gives the weight of the specimen used. If whole blood is studied, it is placed directly on the filter paper from the puncture wound in the finger. After weighing the sheet of filter paper is allowed to dry until the moist stain disappears and the material is then placed in a dry glass receptacle. The paper must be dry enough so that none of the specimen sticks to the glass. Similar sheets are prepared for control weighings. After weighing, the next step of the analysis is carried out. Bang's method has been used for blood sugar and chloride determinations and for the Kjeldahl determination of nitrogen. The technic has certain disadvantages for use in this country. The torsion balance is costly and must be carefully checked from time to time. Modifications of the method have been introduced in which instead of the weighing, the fluid is quantitatively determined by microvolumetric apparatus and delivered to the filter paper. The filter paper must be of the proper quality and certified before its use. As a result of these difficulties, no American textbook on quantitative clinical chemistry methods includes Bang's technic. The recent revision of Sahli's *Lehrbuch der klinischen Untersuchungsmethoden* 1931 volume II second half gives the technic for micro-Kjeldahl sugar and chloride determinations in detail on pages 590, 597 and 617.

PHARMACOLOGY OF POTASSIUM CHLORIDE

To the Editor—The Council on Pharmacy and Chemistry in reporting on Hosal (THE JOURNAL July 22, p. 280) states that the referee's associate added that a colleague has used potassium chloride in long standing cases of nephritic edema without harmful effects over long periods. Potassium chloride is omitted from the materia medica books at my disposal. Will you kindly discuss the pharmacology of potassium chloride with special reference to its use in nephritis? What authorities sanction its use? Please omit name.

M.D. New York

ANSWER—It has long been known that the heart is poisoned by an excess of potassium salts in the circulation though a small amount is necessary for its action. It has also long been known that relatively large doses of these salts may be administered orally, or even by slow intravenous injection in normal animals or man without injury and it has been assumed by some that elimination by the kidneys explains the tolerance of such large doses. The corollary of that assumption is that the potassium salts are more toxic in the presence of nephritis than when the kidneys are normal. This is true as a general statement but not under all circumstances.

The blood is capable of eliminating many substances with great rapidity by various means and the kidneys in a given case may play a minor part in this elimination. Dr. Gold has recently observed (unpublished report of experiments) that no less than five times as much potassium chloride could be injected intravenously in a normal animal in five minutes without causing death as could be injected within half a minute.

It is obvious that the role of the kidneys is a minor one in the elimination of potassium salts from the circulation in such a short time and Dr. Gold observed no perceptible difference in the total intravenous dose of potassium chloride in the normal and in the nephrectomized animal with rapid injection. The inference hence that the potassium salts passed from the blood serum into the tissues including the corpuscles.

The case is entirely different when large and frequently repeated doses are given orally over considerable periods, because there is a limit to the amount of the salts that may diffuse into the tissues and prevent the concentration in the blood serum that is injurious to the heart, in short, one should never administer the potassium salts in such a way that the concentration in the blood serum is greatly increased above the normal, and, on the other hand, if this increase is prevented, considerable amounts often may be given without harm.

Many seemingly contradictory statements in the literature may be harmonized if one bears in mind that many factors influence the actual toxicity of potassium salts for the heart, and that the concentration in the blood serum is also determined by a variety of conditions including the rate of absorption and the rate of elimination, each of which, in turn, is influenced by many conditions.

The use of potassium salts in the treatment of certain cardiac arrhythmias has been discussed by Samson and Anderson (THE JOURNAL, Dec. 31, 1932, p. 2257) and Smilhe (Arch. Int. Med. 16:330 [Aug.] 1915) observed acute poisoning resulting from 10 Gm. of potassium chloride in one patient who had chronic nephritis. These authors give numerous references to the literature which should be consulted by one who wishes to use one of the potassium salts therapeutically.

SATO TECHNIC FOR PEROXIDASE REACTION OF BLOOD CELLS

To the Editor—Would you kindly give me the technic of making peroxidase blood smears by the method of Sato. This is referred to in THE JOURNAL, July 12, page 251 but the technic is not included. Please omit name.

M.D. Ohio

ANSWER—The Sato technic for the peroxidase reaction of the blood cells is a valuable improvement over the earlier methods. The technic and a critical analysis of the procedure are presented by Mascher in the *Zeitschrift für klinische Medizin* for May, 1933.

The following solutions are needed: (1) copper sulphate solution, 0.5 per cent, (2) 0.2 Gm. of benzidin dissolved in 200 cc. of distilled water at room temperature with the addition of 4 drops of 3 per cent hydrogen dioxide after filtering, (3) 1 per cent aqueous safranin solution as a nuclear stain.

The dioxide solution should be fresh. The benzidin solution should be a saturated solution. To test the solution, equal parts of solutions 1 and 2 are mixed in a test tube. A deep blue should appear immediately. Solution 2 should be kept in a dark cool place. It keeps for about six months.

The staining technic is as follows. The freshly prepared blood smears are allowed to dry in the air. Methyl alcohol should be avoided in cleaning the slides or cover slips. Solution 1 is first added for two minutes, poured off without washing and then solution 2 added for one and one-half minutes. The smears are carefully washed with a slow stream of water, and stained with solution 3 for two minutes. They are then washed and dried in the air. The technic is simple and the preparations keep indefinitely.

The peroxidase granules of the granulocytes (of bone marrow origin) assume a deep blue-green. The nuclei of the cells and the lymphocytes are red. The red cells do not stain.

This stain is highly sensitive owing to the presence of the copper sulphate. Not only the myeloid cells but also the monocytes show peroxidase granules. Therefore the Sato stain easily differentiates the myelogenic from the nonmyelogenic blood cells.

NONSPECIFIC TREATMENT OF HYPERSENSITIVENESS

To the Editor—I have a case of persistent urticaria in which diets and test diets have failed to give satisfactory evidence of a specific cause. Will you please outline all known methods with references for the non-specific treatment of hyper-sensitiveness? I have already used ephedrine, ephedrine and atropine but the relief is temporary and the side actions are becoming increasingly unpleasant. What is the present status of calcium and arsenic? Please omit name.

M.D. New York

ANSWER—Several other investigations in addition to those mentioned are suggested as a guide to the treatment of this case. Chronic infections especially those of the teeth and the gallbladder play a not infrequent part in the causation of urticaria. Gastrointestinal factors should be investigated especially the possible presence of a hypochlorhydria. In an occasional case a thyroid deficiency, as found by basal metabolism determination points the way to the appropriate remedy. In addition to food factors one should also investigate the possibility of physical allergy—due to heat or cold. Many instances are markedly aggravated by nervous and psychic factors and some persons seem to have the condition caused entirely by emotional disturbances.

If these investigations have yielded no response, less specific means should be tried. It will be possible to describe only a few of the methods here. Calcium lactate or gluconate orally or calcium gluconate or chloride intravenously is of help in some instances, although the blood serum in urticaria does not show a calcium deficiency. Parathyroid extract-Collip, from 4 to 8 units subcutaneously, given at first every day and then less frequently, has been of great benefit in many cases. Some report gratifying results from autohemotherapy. The action of bacterial vaccines is probably a nonspecific one. Five-tenths gram of peptone taken from half an hour to an hour before each meal produces temporary desensitization in some instances. A more drastic measure, which may be tried in a desperate case is fever therapy.

Dilute hydrochloric acid or urea nitrate from 0.2 to 0.4 Gm with each meal helps at times. A diet poor in sodium chloride has been recommended. Sedatives to allay the irritation and itching are frequently indicated. Salicylates are sometimes of value. There is nothing of any established value in the use of arsenic.

TREATMENT OF HOOKWORM DISEASE

To the Editor—Please give me the safest drugs for use in the treatment of hookworm disease. In your opinion what is advisable as to both efficiency and safety in the use of ferrous sulphate as advised by Colby and Schaffie? Please omit name.

M D Georgia

ANSWER—Of the thoroughly tested anthelmintics carbon tetrachloride is probably the most effective and, if properly controlled, the least toxic. It is however in common with thymol, chenopodium and other well known drugs, quite toxic under certain conditions. It can be given in large quantities to man and animals in proper calcium balance but if sufficient calcium is lacking a grumbling intoxication follows often resulting in death. This can be controlled by proper calcium therapy. For adults, carbon tetrachloride is generally given in doses of 3 cc, but some use as low as 1.5 cc or as high as 5 or even 10 cc. Treatment should never be repeated in less than a week. It can be given in capsules or in water or milk and is generally followed within an hour by a magnesium sulphate purge. Carbon tetrachloride is not so effective against *Ascaris*, and when both worms are present many workers give carbon tetrachloride mixed with oil of chenopodium—as for example 2 cc of carbon tetrachloride and 1.25 cc of oil of chenopodium.

Among the more recent drugs that give great promise is hexylresorcinol, which apparently not only removes hookworms but *Ascaris* and to a less extent trichurias and possibly tapeworms. Patients of 12 years or above are given 1 Gm and children 0.5 Gm. It is administered best in the morning on an empty stomach without food for four or five hours. A saline purge is often given but is not necessary. Although practically nontoxic it exerts a local irritant action if chewed in the mouth. Gelatin capsules cannot be used and various oils and syrups are unsatisfactory. The best method of administration is a pill made by Sharp and Dolime, in which the crystals are rolled into a ball and coated with sugar.

We do not know of any conclusive demonstration of the effectiveness of ferrous sulphate.

TREATMENT OF LUPUS VULGARIS

To the Editor—Kindly inform me whether in recent years there has been any new development in the treatment of lupus vulgaris aside from the usual methods described in textbooks such as ultraviolet radiation, x-rays and radium along with general supporting measures. An American woman afflicted with this condition and resident in Brazil has asked advice concerning the possibility of returning to New York for the purpose of taking intravenous injections of some gold compound which is entirely unknown to me. The patient believes that these injections have benefited her in the past. I should appreciate advice on the latest methods in the treatment of lupus in order that I may intelligently refer the patient to the source of the best available treatment. Please do not publish my name.

M D Brazil

ANSWER—The most valuable recent addition to the therapy of lupus vulgaris is the Gerson-Hermansdorfer-Sauerbruch diet, in which salt is restricted as much as possible, a sodium-free substitute being used to flavor the food. Meats are also restricted, but milk and eggs are given freely and raw fruits and vegetables and their juices are pushed. Cooked fruits and vegetables are also used and phosphorized cod liver oil is given. This has a decided effect on the general metabolism but a much greater one on the skin, reducing the sodium content and consequently the water. Calcium and magnesium are also reduced but are supplied as medicine. Potassium is increased in the skin. This raises the resistance of the skin and many cases of lupus vulgaris that have resisted ordinary treatment are cured by the diet alone, others being cured by diet and

local treatment. Several or many months are required for the full benefit to appear.

Dr Dorff (Proc Staff Meet, Mayo Clin 7 73 [Feb 10] 1932), who has studied the effects of this diet thoroughly, believes that it in many cases increases the sensitivity of the skin to old tuberculin, ultraviolet rays, chrysarobin, croton oil and mustard. The Gerson-Hermansdorfer diet was described in the Berlin letter in THE JOURNAL, Sept 14, 1929, page 861.

Founded on the discovery of Koch that gold cyanide is the most active deterrent to growth on culture medium of the tubercle bacillus, gold salts have been given intravenously in the treatment of various forms of tuberculosis for some time. Their effects have been disappointing except in lupus erythematosus in which they have been so successful that they are now regarded as the chief treatment. They fail to benefit some cases of lupus erythematosus and are still more often disappointing in lupus vulgaris. After much experience the dose has been reduced. Of gold sodium thiosulphate used generally in the United States, the maximum dose is 0.1 Gm, and excellent results from smaller doses are obtained in many cases. It is given once a week for from ten to twenty, sometimes more, weeks. All precautions against kidney, liver or skin irritation must be taken just as in the case of the arsphenamines. Untoward symptoms from overdosage of the gold salts resemble closely those from arsphenamine.

HYPEREMESIS AND ATTEMPTED ABORTION

To the Editor—One of my patients has been subjected to vomiting every morning and sometimes during the day. Although this is only one of the symptoms of pregnancy, it is more severe than in the usual case. She has a history of repeated attempts at abortion, none of which were successful. March 12, one month from the time of conception, she took manganese dioxide. Two weeks later she tried a compound of aloin and castor oil and finally she took some ergotinapiol pills. All of these chemicals produced only stomach pains. She is only 18 and this is her first experience of this kind. Being in desperation she had an attempt made of emptying the uterus by mechanical means—tamponage. With her cervix packed for about eleven hours she lived in fright. At the end of that time she pulled out all the gauze. There have been no symptoms of septicemia. The vagina and cervix on examination appear normal. Is there any connection between this vomiting and attempts at abortion? Will attempts such as these affect the child in any way? At no time did anything pierce or go into the uterus any farther than the internal orifice of the uterus.

M D

ANSWER—The vomiting in this case is not due to the repeated attempts to produce abortion. Both the vomiting and the efforts to terminate the pregnancy are manifestations that the patient does not want to remain pregnant. The former is unconscious and the latter deliberate but the two give the same information in this particular individual. It is well known that in most cases of severe vomiting of pregnancy, the true cause of hyperemesis gravidarum is a large psychic element. This is distinctly true in the early stages of hyperemesis before the toxic symptoms arise from starvation and other causes. Because of this, some patients with hyperemesis can be cured at the beginning of the illness by means of suggestive therapy alone.

The repeated efforts of this patient prove that it is usually impossible to disrupt a normal gestation by drugs and even by mechanical measures unless the latter invade the uterine cavity. The means which this patient used, including the gauze packing in the cervix, almost certainly have not had deleterious effect on the development of the fetus. Nearly always when the ovum is harmed during the early months of gestation it is expelled spontaneously.

MULTIPLE EMBOLI

To the Editor—I have recently seen a Gentile woman aged 48 who gave a history of having her arm suddenly drop to her side while sweeping. It turned blue and remained pulseless for five weeks with constant pain. Spontaneous recovery ensued except for absent pulse and incomplete function. Some weeks later the patient had an attack of violent abdominal pain with vomiting two weeks after which pain developed in the opposite foot. She was treated for rheumatism and neuritis. After several weeks the foot became blue but with no white or red stage and partial spontaneous recovery occurred though the patient was unable to walk. At present a second attack in the same foot of gradual onset covering several hours has occurred. The foot is mottled blue and white, blanching on elevation except the sole. Only one side is involved. The patient's temperature is 100. Diagnosis of Raynaud's disease was made by some one also the more colorful one of Buerger's disease while the country doctor let it go at emboli. Your opinion will be gratefully appreciated. Please omit name.

M D Michigan

ANSWER—The disappearance of pulsation in the arm, with changes in color, is probably due to arterial occlusion. The fact that this occlusive process is multiple, probably in the arteries of the abdomen and lower part of a leg makes the diagnosis of embolism tenable. The pain is apparently sec-

ondary to ischemia, probably ischemic neuritis. Emboli usually are one of three types: (1) detached mural thrombi or vegetative thrombi from the heart such as are seen in valvular diseases or in auricular fibrillation, (2) the multiple products of spontaneous simple thrombosis, the origin of which is probably some disturbance in the coagulability of the blood, (3) in older subjects detached thrombi from arteriosclerotic plaques on the larger arteries. The rapid course seems to rule out the more chronic arterial occlusive lesions, such as thromboangitis obliterans or arteriosclerotic disease.

TREATMENT OF DIABETES

To the Editor—A diabetic woman aged 35 married who is of the Lorrain Levi type 4 feet 8 inches (142 cm) tall weighed 59 pounds (27 kg) when I first saw her about one year ago. Her mother died in diabetic coma. The patient had not worked for a year. She had not menstruated for two years and her nails had almost completely degenerated. She was acidotic. She was placed on a high carbohydrate and protein diet with large doses of insulin and went back to work in three months. Her nails have completely regenerated and her menstrual function returned with a normal rhythm four months ago. She now weighs 123 pounds (56 kg) is well rounded and never felt so well in all her life. Her status has been determined as almost totally diabetic. Here is the problem. She is now on a diet of 110 Gm carbohydrate, 45 Gm protein and 60 Gm fat with 130 units of insulin daily. She always has a blood sugar above 200 and excretes from 0.5 to 4 per cent of sugar in the twenty-four hour specimen. In spite of fractionation of urines and regulated insulin dosage I have been unable to change this status. There is no evidence of kidney damage, no disturbance of pancreatic function and no complaints. At times her blood sugar is above 300. I have definitely established that there is no cheating yet I cannot account for the wide fluctuation. Is there a pancreatic adenoma? What can be done? Please omit name.

M D New York

ANSWER—Certainly there is no evidence of a pancreatic adenoma in this interesting case. In all previously reported cases of tumor of the pancreas hypoglycemia rather than hyperglycemia was present. In studying what has been done for this patient, one wonders whether an even higher diet might not be more satisfactory than the one given. It has been noted by many observers that both total calories and carbohydrates may be increased in some diabetic patients without a corresponding increase in the insulin intake. In other words, this means that the insulin sometimes works better when there is a larger amount of carbohydrate to work on. At any rate it is worth trying. The carbohydrate should be raised perhaps 15 or 20 Gm daily without at first increasing the insulin.

INTERCOSTAL NEURITIS ASSOCIATED WITH INJURED CARTILAGE

To the Editor—I should like your opinion on the following case. A girl aged 19 complains of pain and occasional swelling in the region of the left lower anterior ribs of a year's duration. She received a blow in that region a year ago. Palpation reveals a loose cartilage. Roentgen examination is negative of course. Will diathermy and strapping bring complete relief? Is surgery ever used in these cases?

A VANDER LÉON M D New York

ANSWER—The occurrence of pain and swelling in the region of the left lower ribs anteriorly following an injury is not unusual. The swelling is probably due to a prominence of the end of the cartilage which has been torn loose. There is an intercostal neuritis, probably due to displacement of the cartilage with tension on the nerve. Strapping of the region with adhesive plaster may give relief and may be discontinued after a short time. Diathermy may be tried for a short time. If no relief is obtained injection of the intercostal nerve with procaine hydrochloride followed by a little 95 per cent alcohol may give relief. As a rule nothing need be done for the loose cartilage, as the condition usually is without symptoms. If injection of the nerve is not feasible it may be cut down on and either injected with alcohol alone or cut in addition to the injection.

DERMATITIS IN SILK INDUSTRY

To the Editor—Please advise me what forms of dermatitis occur in employees of silk mills and whether or not there is a book published describing the forms of the skin conditions caused from working in a silk industry.

J ORIS LIVEN M D Almore Ala

ANSWER—Starting with the raw silk it is possible that a dermatitis may be produced by the silk glue sericin, which is easily removed in the silk manipulative processes usually by hot solutions of soap and (or) alkalis. Thereafter in many stages of silk preparation various chemicals are used in weighting, lustering, delustering, sizing and finishing. Scores of chemicals and combinations of chemicals are employed. Nearly every plant utilizes slightly different processes, many of them

guarded as trade secrets. Later, in preparation for dyeing and in dyeing, many other chemicals are employed.

In the making of artificial silk, in contrast to natural silk, the number of chemicals employed is usually higher, and prospects of dermatitis are always greater. Among other substances that have been used, in natural or artificial silk manufacture or in both, are thiosulphates, Irish moss, formaldehyde-phenolic resins, diethylphthalate, xylene sulphonamide, paratoluene sulphonamide, monomethyl-xylene sulphonamide, beeswax, tragacanth, spermaceti, cetyl alcohol, Japan wax, stearic acid, acacia (gum arabic), gelatin, turkey red and various other oils, polysulphates, trichlorethylene, sodium carbonate, sodium sulphate, magnesium chloride, dextrans, kana gum, starch, mineral acids and organic acids.

It is not known that books devoted to dermatoses in this industry have been written. More information may be gained by referring to comprehensive treatises of the silk and rayon industries in which are listed various chemical substances that have been found to be serviceable toward industrial ends. It will be readily recognized that many of these chemicals are skin irritants and that suitable exposure may be followed by chemical dermatitis.

DEAFNESS FOLLOWING INFECTION OF VESTIBULE

To the Editor—Can you suggest a treatment that will help in a case of infection of the vestibule? The infection occurred when the patient was traveling on a badly ventilated train over a year ago. When the patient awoke in the morning there was an acute coryza, fever and chill. Within twenty-four hours it had spread to the middle ear and caused deafness and headache with fever. A week in a hospital relieved the general symptoms but deafness continued about three months and was accompanied by giddiness and other symptoms of involvement of the vestibule. The eustachian tubes continued to be occluded until quite recently. Even now the passage of the eustachian catheter is not altogether satisfactory. The specialist attending does not think that he can do any more to relieve the condition. The present condition is perforation of the right drum from childhood, no discharge occurs but there is very little hearing. The left drum is now healthy looking. There is no discharge or discomfort in the nose. The voice sounds go out through the right ear and the voice does not seem right. Musical notes sound out through the right ear and not of the correct note. There is no giddiness now. Confusion and deafness occur when the patient is in a room full of people or in the presence of much noise. Please omit name.

M D Newfoundland

ANSWER—It is quite possible to have involvement of both the cochlear and the vestibular apparatus of the inner ear, as a result of a toxemia resulting from some acute infection. Complete functional testing of the hearing would show whether at the present time there is still considerable impairment of the inner ear or whether it is the conduction apparatus that is having the trouble. If it is involvement of the perception apparatus the use of an alternative such as potassium iodide, might be of some service. For the relief of the difficulty in the right ear which has been present since childhood it is doubtful whether much can be done. "Confusion and deafness when in a room full of people or in the presence of much noise" is usually noted when there is a marked impairment of hearing. It is possible that the use of a proper aid to hearing would be of service in this condition.

UNILATERAL CYANOSIS

To the Editor—I would be pleased if you could give me some help as to the etiology of unilateral cyanosis limited to the left hand, forearm and arm. The case is one of a 4 months old infant previously healthy in every respect. The mother observed that when the child was placed on its abdomen the hand became blue then the forearm and arm. The phenomena occur in less than two minutes and when the child is placed in the dorsal position the cyanosis clears up. There is no associated pain and the child is contented and happy. Roentgen examination of the chest is negative and no palpable masses can be elicited in the axilla. Kindly omit name.

M D West Virginia

ANSWER—Unilateral cyanosis in an infant suggests the following possibilities: 1. Congenital dilatation of the veins, the so-called phlebectasia. This condition usually carries with it no serious significance and is symptomless. 2. Venous obstruction such as that caused by congenital anomaly of the cervical rib. The fact that this condition changes with changes in posture raises the possibility of some anomaly of the bony structures of the neck. 3. Pressure from a new growth. This seems fairly well ruled out by the fact that the cyanosis can be modified by the posture of the child.

There is one additional condition to consider, arteriovenous fistula in which there is distention of the veins from an abnormal communication with the arteries. In this condition the affected extremity would be hotter than the opposite and the veins would contain arterial blood.

Thrombophlebitis seems eliminated by the absence of swelling.

BRONCHOMONILIASIS

To the Editor—A woman aged 22, single gives a history not unlike that of insidious tuberculosis—chronic fatigue, pain over the upper part of the chest, hoarseness, afternoon elevation of temperature and blood tinged sputum. Physical examination of the chest gives negative result. Roentgen examination of the chest made at the local tuberculosis hospital and also by the state examining chest clinic showed no pulmonary pathologic changes. Repeated examinations were negative. Repeated sputum examinations were negative for tubercle bacilli. The state department of health, however, found on sputum testing a yeastlike microorganism resembling *Monilia*. Other specimens of sputum were tested for and the final report sent me was that the yeastlike microorganisms were a *monilia* which proved to be pathologic for white rats. Can this organism be the cause of the symptoms in this case? There are no symptoms of sprue with which *Monilia* is mostly associated. I can find no description in tests of similar conditions being produced by *Monilia*. Please omit name.

M D New York

ANSWER—This case could easily be one of what Castellani has called bronchomoniliasis, but it is either a mildly virulent or a beginning case, for usually there are physical signs of localized lesions confirmed by x-ray shadows. The important finding here is a *monilia* pathogenic for white rats. Such a *monilia* is apt to be *Monilia albicans* as this is a pathogenic organism not only of thrush but also of sprue, bronchomoniliasis and moniliasis of the skin. Ashford writes that he no longer believes in his own *Monilia psilosis* or in Castellani's many pathogenic species as entitled to separate designations and believes that all these pathogenic species should be referred to as *Monilia albicans* until some other method than that by sugar fermentation tests becomes available to show differential characteristics. The reader is referred to the article of T. R. Boggs and M. C. Pincoffs entitled "A Case of Pulmonary Moniliasis in the United States" (*71 A. Am. Phys.* 30:474, 1915 *Bull. Johns Hopkins Hosp.* 26:407, 1915).

INDICATIONS FOR CALDWELL-LUC ANTRUM OPERATION

To the Editor—What are the indications for the Caldwell-Luc antrum operation? Is it now commonly done? Please omit name.

M D, Indiana

ANSWER—The Caldwell-Luc operation on the maxillary sinus is used quite frequently at the present time. When a chronic infection of the antrum of Highmore is not relieved or improved by relatively simple procedures such as making an opening into the antrum by way of the inferior meatus, it is advisable to do an operation of the Caldwell-Luc or similar type, in order that a complete inspection of the antral cavity may be had. Not only when a definite suppuration is present but in cases of polyp formation or when a neoplasm is suspected, inspection of the maxillary sinus, by way of the canine fossa, offers the best opportunity for making a definite diagnosis before removing pathologic tissue.

TRENDELENBURG TESTS OF VARICOSE VEINS

To the Editor—In his book, *Varicose Veins*, McPheeters states in conclusion "any vein which shows a positive negative double or nil Trendelenburg and which does not increase in size and cause pain when tested with the tourniquet or bandage while walking should be injected. If this is true why all the ado about doing such a test before injecting in these cases?" Please omit name.

M D Pennsylvania

ANSWER—Dr. McPheeters writes: "As the subject being discussed was varicose veins, I took it for granted and assumed that any reader of this test would draw the same conclusion. Certainly no physician would assume that I was meaning normal veins."

Apparently the writer making the inquiry did not carefully read that paragraph. It is accurate and clear and I approve of the test as being more positive and convincing now than when the paragraph was first written. It might be more clear and emphatic if I had said "Any varicose vein which DOES increase in size and cause pain with the tourniquet or bandage applied while walking should NOT be injected. It must be remembered that all these tests are for the BORDERLINE case only and need not be used in each and every case before beginning treatment."

TECHNIC OF CLEARING EMBRYOS

To the Editor—I have spent some time trying to find an account of the technique used in clearing embryos by the use of methyl salicylate. I would appreciate it if you could direct me to a reference or outline the technique for me.

DONALD A. LAIRD, Hamilton N. Y.

Director, Psychological Laboratory, Colgate University

ANSWER—Inject the vessels, if desired. Fix in solution of formaldehyde. Wash out the formaldehyde thoroughly. Bleach in hydrogen dioxide. Run through alcohols up to 100 per cent.

Immerse in benzene. Change two or three times. For large embryos, methyl salicylate 2 parts and benzyl benzoate 1 part or methyl salicylate 18 parts and isosafrol 5 parts are used. For smaller embryos, methyl salicylate 3 parts and benzyl benzoate 1 part or methyl salicylate 27 parts and isosafrol 5 parts. For very small embryos, methyl salicylate 5 parts and benzyl benzoate 1 part or methyl salicylate 9 parts and isosafrol 1 part are used. Pump out with an air pump to get rid of air and benzene. Preserve in the fluid last used. Other methods also are reported by Rönne. Taschenbuch mikroskopischen Technik, Berlin, R. Oldenbourg. Sold in America by G. E. Stechert, 31 East Tenth Street, New York.

DETERMINATION OF BLOOD UREA

To the Editor—Will you please advise me as to the value of the modified blood urea nitrogen micro-method of W. G. Karr. The method uses gum glutathione and nesslerization of protein free filtrate. Is this method as good as the methods using the mercury combining power of blood as an index such as the Hensch Aldrich? Please omit name and address.

M D Kansas

ANSWER—The Taylor-Blair modification of the Karr procedure for blood urea nitrogen by direct nesslerization is no doubt an improvement on the Karr method and appears to compare favorably with the older standard aeration and distillation methods after urease action. The method is more specific for urea than the Hensch Aldrich procedure for urea in saliva or urine.

POSTHERPETIC NEURALGIA

To the Editor—Will you please tell me if there is any method of treating a postherpetic neuralgia aside from local applications of cocaine ointment and morphine. Please omit name.

M D New York

ANSWER—In spite of the fact that the lesion in postherpetic neuralgia is in the ganglion, experience has shown that some times considerable benefit has been obtained from injection of the nerve concerned at its foramen of exit. Thus, cases of supra-orbital herpes may be improved by injection in the supra-orbital foramen. Cases of intercostal lumbar neuralgia may be improved by injection of procaine hydrochloride followed by salt solution or dilute alcohol at the corresponding intervertebral foramina.

FEEDING OF BILE AFTER BILIARY DRAINAGE

To the Editor—Kindly advise me regarding the feeding of bile back to the patient as it drains out from a cholecystostomy tube. The patient has a tumor obstructing the common duct which is inoperable and a tube was placed in the gallbladder for drainage. Would it not be well to give her that bile by mouth once or twice a day? Please omit name.

M D Kentucky

ANSWER—Yes. This is particularly advisable when biliary drainage is continued for a long period, because by its use severe anemia may be prevented. In the case mentioned here it probably does not make much difference if the lesion is a malignant tumor.

ELECTRORESECTION OF THE PROSTATE

To the Editor—I have a friend who is suffering with a slight enlargement of the prostate. Is the galvanocautery treatment of choice in cases of slight enlargement of the prostate or has the cautery operation superseded prostatectomy? Please omit name.

M D Canal Zone

ANSWER—Transurethral electroresection is considered the operation of choice by many urologists in the correction of small and moderate sized enlargements of the prostate gland. Some are even employing this method in the treatment of the larger hypertrophies.

DUOCHROME DISC FOR REFRACTION

To the Editor—I have received a circular on the Sears Duo-Chrome Disc for duo-chrome refraction. Please advise me as to the practical merits of this method of refraction?

J. B. H. Waring, M D, Wilmington, Ohio

ANSWER—The Sears Duo-Chrome Disc is merely another device on the market trying to substitute a manifest refraction for conscientious refraction with cycloplegia. Accommodation is not and cannot be suspended by this or any similar device and as long as accommodation is one of the decisive factors of careful refraction, cycloplegia cannot be dispensed with. If the refractonist is satisfied with by-guess methods, he can come as near to the actual refractive error with the duo-chrome disc as he can with any of the other methods of the drugless glass-fitter.

Massachusetts May Examination

Dr Stephen Rushmore, secretary, Massachusetts Board of Registration in Medicine, reports the oral and written examination held May 23-25 1933. The examination included 64 questions. An average of 75 per cent was required to pass. Ninety-eight candidates were examined, 34 of whom passed and 64 failed. The following colleges were represented:

College	PASSED	Year Grad	Per Cent
Yale University School of Medicine		(1919)	75
Fumoy University School of Medicine		(1928)	75
Boston University School of Medicine		(1932)	75.3

* Examined in medicine and surgery

Missouri June Examination

Dr E T McGaugh state health commissioner, reports the written examination held in St Louis, June 7-9, 1933. The examination covered 14 subjects and included 97 questions. An average of 75 per cent was required to pass. Two hundred and one candidates were examined, all of whom passed. Sixteen physicians were licensed by reciprocity and 3 by endorsement. The following colleges were represented:

Book Notices

The Therapeutic Agents of the Quinoline Group Cinchophen, Plasmoquine, Nupercaine, Quinine and Acridine Dyes: the Relation Between Their Chemical Constitution and Pharmacologic Action. By W. I. von Oettingen, M.D., Ph.D., Assistant Professor of Pharmacology, School of Medicine, Western Reserve University, Cleveland, Ohio. American Chemical Society Monograph Series No. 61. Cloth. Price \$6. Pp. 301 with 10 illustrations. New York: Chemical Catalog Company, Inc. 1933.

Chemical agents derived from the quinoline nucleus have found wide usage in therapeutics. Such common and well known drugs as quinine and its derivatives, oxyquinoline sulphate, cinchophen, nupercaine and the acriflavines are related to quinoline. With the exception of quinine and its naturally occurring chemical relations, most of the drugs in the quinoline group are the result of laboratory investigation. Many of them have been produced and found their usefulness since the World War. The chemical and the pharmacologic and therapeutic literature on this group of drugs of diverse use is widely scattered in the chemical, pharmacologic and medical literature. Dr. von Oettingen has made a worth-while contribution to the literature of chemistry, pharmacology and therapeutics by collecting between two covers this widely scattered information. The book, however, is not a mere compilation of data. It is a careful attempt to correlate, whenever the data permit, the ground already gained and, even more important, the path along which future progress may be made. The material in the book will be of little interest to the general practitioner, but for the practitioner interested in the manner by which drugs are therapeutically established there will be much information. Here the book should be welcome to the thoughtful practitioner, particularly in respect to such drugs as cinchophen, the importance of which both as an agent for good and as an agent for harm has already been appreciated, and nupercaine, as representative of the group of local anesthetics derived from quinoline. For the investigator on chemistry and drug action there is much of value, here the book should be welcome and extremely useful. The author understands not only pharmacology but also chemistry and medicine. It was indeed fortunate that the American Chemical Society could obtain one of Dr. von Oettingen's versatility to handle such a restricted field as that of the quinoline group. There are a number of tables and charts, summarizing the literature, apart from the descriptive material. This book is one of a series of monographs published under the auspices of the American Chemical Society. It indicates the close dependence of medicine on chemistry.

Röntgenatlas der Lungenkrankungen Ein Leitfaden für Ärzte. Von Dr. W. Brednow, Privatdozent für innere Medizin und Röntgenologie an der Universität Göttingen, und Dr. F. Hofmann, Facharzt für Röntgenologie, Stadt Krankenhaus Wuppertal-Barmen. Second edition. Paper. Price 10.00 marks. Pp. 207 with 105 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1933.

This atlas consists of a collection of more than a hundred excellent full-page reproductions of roentgenograms illustrating normal and abnormal conditions of the lungs. The value of the reproductions is greatly enhanced by the accompanying legends, which point out the changes to be observed and their significance. Since the book is designed primarily for the general practitioner, it contains concise information about the course of various diseases, certain favorable and unfavorable changes that may occur during the progress of the condition, and therapeutic hints, particularly section of the phrenic nerve, and collapse treatment. It is pointed out that several disease conditions may produce similar roentgenographic changes and that a final diagnosis of pulmonary disease should not be based on a roentgenogram alone. The material is so arranged that normal aspects are first described. Then follows a rather complete presentation of pulmonary tuberculosis. The value of oblique exposures is emphasized in certain obscure instances. Nontuberculous conditions such as pneumonia, pulmonary infarct, abscess, silicosis, tumor and pleural diseases are then illustrated and described. The value of the book would be enhanced by including some reproductions of bronchography. Some of the changes of the pleura shown in the illustrations are not very distinct. This atlas is in every sense a useful and practical aid for the clinician for whom it is primarily designed rather than for the expert roentgenologist.

Operative Surgery The Abdomen and Rectum By Dr. Martin Kirschner, Ordinaris Professor of Surgery and Director of the Surgical Clinic at the University of Tübingen (Germany). Volume 2. Authorized translation by I. S. Haydin, B.S., M.D., J. William White, Professor of Research Surgery, University of Pennsylvania. Cloth. Price \$10. Pp. 569 with 395 illustrations. Philadelphia: J. B. Lippincott Company, 1933.

The second volume of Kirschner's Operative Surgery, appearing two years after the first, which was received enthusiastically, equals it in quality and appearance. This one deals with the various conditions affecting the abdomen and rectum and covers the field thoroughly and completely in seven chapters. The careful consideration of abdominal incisions and operative procedures on the gastro-intestinal tract is followed by an extensive description of the various operations on the stomach and duodenum. The operations on the small and large intestines, as well as on the rectum, including the procedures to be followed in cases of mechanical and paralytic ileus, are treated in great detail. The same may be said of the discussion of the operations on the gallbladder and parenchymatous abdominal organs which concludes the work. The subjects treated are fully covered, clearly presented and easy to follow, enhanced no doubt by the excellence of the translation. The numerous beautiful illustrations, mostly in color, which clarify and emphasize the important points in the text, are the great feature of the book. The work is an unusually excellent contribution and is highly recommended to young as well as experienced surgeons.

Ophothérapie endocrinienne Les bases physiologiques les syndromes la posologie de l'opothérapie. Par Guy Laroche, professeur agrégé à la Faculté de médecine de Paris. Second edition. Paper. 48 francs. Pp. 396 with 19 illustrations. Paris: Masson & Cie, 1933.

A chapter on liver therapy in pernicious anemia has been added and the chapter on the pancreas and insulin revised and enlarged, but the book is still mediocre and of little help to practitioners or research men in this country. There is too little critical evaluation of the thousands of trials, suggestions and recommendations for organotherapy in human disorders, many of them unverified or disproved. Thus the author outlines ovarian organotherapy in toxic goiter, chronic rheumatism and virilism.

Filterable Virus Diseases in Man By Joseph Fine, M.D., B.Sc., D.P.H., Assistant to the Prof. of Public Health, Edinburgh University. Cloth. Price \$2.25. Pp. 144. Baltimore: William Wood & Company, 1930.

This book gives in compact form the essential facts concerning the virus diseases in man, of which there are listed twenty-four. They are divided into seven groups, whether transmitted by an intermediate host or directly, and whether affecting the skin, the nervous system or the respiratory system. At the end of each chapter is a short but inclusive bibliography. The author has stated the facts concerning the virus diseases concisely and clearly, when authorities have disagreed, he has given all the pertinent evidence on each side of the question. In a few instances in which there are no universally accepted views, such as the identity of the virus of herpes and of epidemic (lethargic) encephalitis, he has given opinions of his own. Foot-and-mouth disease has been omitted. Two tables at the end of the book should prove useful for quick reference. In one, facts are presented concerning the twenty-four virus diseases of man, while in the other are listed brief accounts of all virus diseases of which there was record at the time of writing, including animals, birds, insects and plants.

Traité de physiologie normale et pathologique Publié sous la direction de G. H. Rogor, professeur honoraire de physiologie à la Faculté de médecine de Paris et Léon Binet, professeur de physiologie à la Faculté de médecine de Paris. Tome IX. Système nerveux première partie. Par MM. Th. Alajouanine, J. Bertrand et autres. Cloth. Price 100 francs. Pp. 566 with 121 illustrations. Paris: Masson & Cie, 1933.

This volume is one of eleven into which the work is divided and is devoted to a review of the knowledge of the nervous system with chapters on the neuron, degeneration and regeneration, nerves and reflex action, tropisms, cortical localization of function, basal ganglia, cerebral circulation, convulsions, sleep, and a biochemical study of general anesthesia. The chapters written by individual contributors, differ markedly in readability, completeness and the handling of references to the literature, but on the whole the volume will be found useful by those who do not read German or are without access to a German handbook of a similar type.

Medical Biology A Laboratory Manual of Bacteriology Mycology Immunology and Parasitology Consisting of Experimental Guide Interpretive Text Atlas and Protocol Form By William Barnard Sharp S.M. M.D. Ph.D. Professor of Bacteriology and Preventive Medicine in the Medical Department of the University of Texas Medical College Edition Paper Price \$4.50 Pp 443 with 111 illustrations Galveston The Author 1933

This laboratory manual was prepared for the special use of students in the University of Texas School of Medicine and therefore does not necessarily fit the arrangement and scope of courses in other institutions, although it is so written that it can be easily adapted elsewhere. The major portion of the volume is taken up with material usually given to medical students in the course in bacteriology. Two chapters of more advanced work are included however on milk and meat product sanitation and on contamination of foods and drinking water. The final chapter deals with medical zoology, covering the subjects of animal parasites, lice, fleas, flies, mosquitoes, venomous reptiles and marine animals. The author has intended that the student write his own textbook as far as limited time and facilities allow. The handbook contains the salient points, reduced to the least possible number of words, which the student might glean from lectures and standard textbooks, to these he adds his own observations. Simple directions are given the student for each procedure. The manual should be useful in the institution for which it was intended.

The Adrenal Cortex A Surgical and Pathological Study By L. R. Broster O.B.E. M.A. D.M. Surgeon to Charing Cross Hospital and H. W. C. Vines M.A. M.D. Pathologist Charing Cross Hospital Institute of Pathology Richards Price 6s Pp 94 with illustrations London H. K. Lewis & Company Ltd 1933

A concise account is given of seven cases of virilism of supposed suprarenal origin in which unilateral suprarenalectomy was done. The regression of the virilism following this operation was slight and variable. Microchemical studies of the suprarenal cortex of these cases are presented, the authors presenting evidence of an increase in the suprarenal cortex of a specific "foamophilic" substance as a causative factor in this type of virilism.

The Practice of Podiatry By Reuben H. Gross M.C.P. Professor of Podiatry The First Institute of Podiatry and E. K. Burnett Edited by Maurice J. Levi M.D. Cloth Price \$6 Pp 451 with 72 illustrations New York Harriman Printing Company Inc 1933

This book contains much excellent material that the podiatrist can use in his everyday practice, and in addition some interesting reading on conditions that he should know but should not treat. The latter include such conditions as osteomyelitis, arthritis, syphilis, tuberculosis, diabetes, arteriosclerosis, thromboangitis obliterans and Raynaud's disease. The discussions of most of these subjects are well condensed. The book contains much more material than its title would indicate. The section on the history of foot gear is interesting.

Gynecology for Nurses By George Gellhorn M.D. F.A.C.S. Professor of Clinical Obstetrics and Gynecology Washington University School of Medicine Second edition Cloth Price \$2 Pp 294 with 140 illustrations Philadelphia & London W. B. Saunders Company 1933

This second edition will be welcomed not by nurses alone but by their medical lecturers as well. That the author is a lucid and graphic teacher is immediately obvious to any one who reads this work. The chapters on constitution and on the endocrine system are valuable additions. The chapter on what the nurse should know about cancer is especially praiseworthy. The book closes with a brief but illuminating account of the history of gynecology.

Pediatrics By Henry Dwight Chapin M.A. M.D. and Lawrence T. Royter M.D. Professor of Pediatrics and Head of the Department of Pediatrics University of Virginia Seventh edition revised and rewritten by Lawrence T. Royter Cloth Price \$7 Pp 770 with 149 illustrations Baltimore William Wood & Company 1933

The former editions of this work appeared under the title of 'Diseases of Infants and Children'. In the present edition there has been an extensive recasting and revision of subjects. The first part of the book deals with the phenomena of growth and development. Few one volume textbooks on pediatrics go into the subject with the detail that this one does. It is concisely presented however and covers only the important phe-

nomena of growth and development that are necessary for a comprehensive understanding. The chapter on appraising the child is excellently done. Criteria of normality are presented with the idea of training the physician to determine the status of the child from an examination, without necessary reference to a fixed standard. The usual subjects found in a pediatric textbook are well covered, and unimportant data have been deleted. An invaluable chapter on the care of dependent infants and children has been included. The Speedwell plan fostered by Dr. Chapin, is clearly explained and discussed. This is a distinct contribution of the work and is unique among pediatric textbooks. The material is well organized and presented in an interesting and concise manner. While it is essentially clinical in its manner of presentation, it has been written with the idea of developing in the reader a better grasp of the problems of the normal as well as of the sick infant and child and will serve the needs of both the physician and the undergraduate equally well.

Beitrag zur Pathologie und Epidemiologie der Pellagra (nach Beobachtungen aus Transkaukasien) Von Priv. Doz. Dr. E. G. Hauck. Beihefte zum Archiv für Schiffs- und Tropenhygiene Pathologie und Therapie exotischer Krankheiten Band XXVII Beiheft 2. Gegründet von C. Menso. Paper Price 3.60 marks Pp 44 with 15 illustrations Leipzig Johann Ambrosius Barth 1933

This small monograph is a summary of studies of pellagra made by the author in Transcaucasia in 1931. It consists principally of epidemiologic and pathologic observations and a discussion of the different theories of etiology which, although adding little that is new, agree with the generally known facts and views concerning this disease. The excellent bibliography should be of value to students of pellagra.

Insects Man's Chief Competitors By W. P. Flint Chief Entomologist Illinois State Natural History Survey and C. L. Metcalf Professor of Entomology in the University of Illinois A Century of Progress Series Cloth Price \$1 Pp 133 with 12 illustrations Baltimore Williams & Wilkins Company [in Cooperation with the Century of Progress Exposition] 1932

This delightful little book recounts the ceaseless warfare between man and insects. To be familiar with all the different kinds of insects, a person must learn the names of 10,000 insects each year over a period of sixty years, while the numbers of each particular kind passes man's ability to estimate. Yet, in spite of these odds, man has learned to survive. The book tells what an insect is, describes the lives and habits of some of them and recounts the advances that man has made, especially in the last hundred years, in the battle against those which transmit disease or produce famine by destruction of food supplies.

Essentials of Prescription Writing By Cary Eggleston M.D. Assistant Professor of Clinical Medicine Cornell University Medical College New York City Fifth edition Cloth Price \$1.50 Pp 155 Philadelphia & London W. B. Saunders Company 1933

The fact that this volume has now seen the fifth edition should speak well of its popularity, which it well deserves as it gives the essentials of the prescribing of medicines in a condensed and convenient form.

Syllabus of Psychiatry A Guide to General Orientation By Leland E. Hinsie M.D. Professor of Clinical Psychiatry College of Physicians and Surgeons Columbia University With a foreword by Clarence O. Cheney M.D. Cloth Price \$2.50 Pp 348 Utica New York State Hospitals Press 1933

Beyond stating that this attempt at a general orientation is well done little in the way of review is practicable. Dr. Hinsie has summarized in a small volume the thoughts, theories and teachings of those whose influence on psychiatry today is of leading significance. They are grouped under chapters on constitutional concepts, psychic concepts, psychophysical concepts and sociological considerations with a final chapter on endogeny and exogeny. On page 332 the author says 'The principal purpose of this syllabus is to build up a new point of vantage from which one may survey psychiatric conditions from which one may gain a critical perspective of the several attitudes in order to see their relationships to one another.' Effort is made to render correlations between the various schools and to throw new light on the position of mental disorders in the field of medicine in general. The sociological chapter con-

tains a syllabus of lectures to social workers in which freudian theory and interpretations are given with an apparent finality in conflict with the author's statement on pages 134 and 135 concerning such concepts that "no one feels at liberty at the present time to suggest that there is anything of a final nature to the conceptions that have been built around the psychiatric disorder." Definite bibliographic references are unfortunately not given. The book is a valuable supplement but not a substitute for textbooks in psychiatry.

Medicolegal

Malpractice Negligence in Interpreting Roentgenogram, Motives of Medical Witness May Be Considered

The plaintiff, while closing a hole in the fourth floor of a building, fell to the second floor. He was removed to a hospital and there attended by the defendant physician. A roentgenogram, taken by means of portable apparatus, was interpreted as showing that no bones were fractured. He remained in the hospital eight days, during which time no additional roentgenogram was made and no treatment was given other than rest and general care. On the eighth day he left the hospital with his physician's consent and with his assurance that no bones were broken. About three weeks after the accident, the injured man consulted other physicians. They found that he was suffering from fractures involving almost the entire structure of the left shoulder. In the end he lost permanently the use of his left arm. In a suit against the physician who attended him in the first instance he obtained a judgment for \$20,000. The physician appealed to the district court of appeals, first district, division I, California.

The expert witnesses for both sides agreed almost unanimously that the roentgenogram made at the hospital was not of the highest type in clarity and detail and that it would not be accepted as a basis for diagnosis by a physician of ordinary skill practicing in the community in which the patient was treated, but notwithstanding this, the evidence showed almost conclusively that it disclosed a fracture. The defendant-physician contended that the interpretation of a roentgenogram involves largely the opinion of the physician who interprets it and that a physician cannot be held accountable for an honest error of judgment. A physician, said the court in forming an opinion and acting on it, is presumed to have the ordinary skill and knowledge possessed by practitioners in his community. Moreover, the existence or nonexistence of things visible to the naked eye is not a matter of opinion. The evidence was sufficient, the court concluded, to warrant the finding by the jury that in making a diagnosis the defendant failed to use and exercise the required degree of care, skill and learning. The claim of the defendant that the roentgenogram on which he relied was clear and good, although lacking in detail, made his unskillfulness only more apparent. His contention that the roentgenogram was made solely to get a chest picture, to visualize the lung condition and to detect possible internal injuries, was regarded by the court as not in point, since the testimony showed that a roentgenogram taken as this one was would necessarily show the shoulder blade, which was fractured. The testimony showed, too, that in the exercise of ordinary skill and care physicians practicing in the community would have called for additional roentgenograms to enable them to determine the patient's condition.

The defendant urged that if the fracture had been discovered it would still have been a matter of personal judgment on his part whether he would or would not treat the patient as he did. This patient, said the court, was detained in the hospital partly to permit the better observation of developments and for further examination. The jury would have been justified, in the opinion of the court in finding that, if the fracture had been discovered, ordinary skill and care required that efforts be made to reduce it. A physician cannot be held liable for mere errors of judgment or for erroneous conclusions on matters of opinion, but he must use the judgment and form the opinions, not of a layman, but of one possessed of skill common to medical men practicing in the same or in a like community.

The fact that a physician has done his best is no answer to an action for malpractice.

Physicians who attended the plaintiff after he left the hospital, testifying for the defendant-physician, said that the plaintiff's condition was not aggravated by the delay in treatment that when the plaintiff came under their care there was no bony union and "the shoulders were in normal apposition" that they found the condition of the plaintiff in all respects the same that would have been present at the outset without aggravation or increased involvement of any sort. They attributed the wasting and loss of power of the shoulder muscles to injuries to the nerves that normally activate them, such injuries resulting directly from the fall and being unconnected with the fractures. Witnesses for the plaintiff, however, attributed the wasting and the loss of power in the shoulder muscles to the faulty union of the broken bones, with the resultant inability of the shoulder muscles to function. There was, said the court, a direct conflict in evidence and manifestly the jury adopted the views of the witnesses for the plaintiff.

The trial court told the jury that it might consider the demeanor of a witness, the reasonableness or unreasonableness of his testimony, his motives, if any, and his interest. Witnesses testifying for the defendant said the court of appeals, displayed a direct interest in the outcome of the case. One testified that he was unalterably opposed to malpractice cases, regardless of the facts. Almost all of them testified that they were acting without fee as a professional duty, to repel the inference that might arise against physicians as a class. Some of the medical witnesses had approached the plaintiff's witness and attempted to intimidate him or at least to dissuade him from testifying under pain of ostracism. Moreover, the physicians who found the nerve injury in the injured man made a report of their examination covering thirty pages or more but in that report they made no mention whatever of any nerve impairment. The same physicians began their treatment by putting the arm into a splint, to remove the bony structure from muscular interference, justifying the obvious inquiry as to what muscular interference could be expected from a muscle already dead. The appellate court could not say what weight the jury gave to the testimony of various witnesses but if the jury concluded that the medical experts were engaged in some sort of a united effort to pull the case out of the fire as a matter of professional pride or interest it would naturally discount their testimony to some extent.

The district court of appeals found itself unable to say that the amount of damages awarded was excessive and being unable to find error in the record affirmed the judgment of the trial court.—*Reynolds v. Struble (Calif.)*, 18 P. (2d) 690.

Workmen's Compensation Acts Compensability of Dermatitis Due to Handling of Dyed Furs—The plaintiff, a saleslady, handled a shipment of low-priced dyed furs, "having a bad odor." Shortly thereafter a rash broke out on different parts of her body. Physicians who examined and treated her testified, in her proceeding for compensation under the workmen's compensation act of Michigan that in their opinion the irritation was caused by handling of the furs. The Supreme Court of Michigan affirmed an award of the department of labor and industry holding that the dermatitis constituted an accidental personal injury arising out of and in the course of the plaintiff's employment.—*Shelman v. Shelman Bros. Apparel Inc. (Mich.)* 247 N. W. 109.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Circulation Time and Sodium Dehydrocholate—Tarr and his associates outline a procedure for the determination of the velocity of the blood flow and the circulation time using sodium dehydrocholate. The test is usually performed in the morning, without breakfast and under resting conditions. The arm is held at the level of the auricles. The tourniquet is applied just before the injection. The patient is instructed that he will experience a transient bitter taste in the mouth and tongue and is to respond at once when he perceives it. The intravenous injection from 3 to 5 cc of a 20 per cent solution of sodium dehydrocholate (the faster the circulation time the less substance is needed to produce the taste), is made rapidly with an 18 gage needle and a 5 or 10 cc. syringe. The time at the start of the injection rather than at the conclusion is taken since the response may come with a minimum amount of the drug. The taste reaction persists for about ten to twenty seconds. The patient's attention can be distracted from any unpleasant feeling afterward by having him breathe deeply for half a minute. The average circulation time is thirteen seconds. The normal range is from ten to sixteen seconds. The authors determined the velocity of the blood in 140 adult patients with heart disease due to hypertension, arteriosclerosis, rheumatic fever or syphilis. There were forty patients in the group without cardiac failure. The circulation time in thirty of these was within normal limits. In the remaining ten the time was between seventeen and twenty-one seconds. There were 100 patients with signs of congestive heart failure. In ninety-six the circulation time was twenty seconds or more and ranged up to forty-seven seconds. In four the circulation time was less than twenty seconds. The velocity of the blood of a group of fifteen children with rheumatic heart disease was investigated. Their general behavior was similar to that of adults. Active rheumatic fever tended to increase the velocity of the blood in two of these children in whom congestive heart failure was present also. The velocity of the blood was determined in patients with congenital heart disease, subacute bacterial endocarditis, paroxysmal cardiac dyspnea, pericardial tumor, paroxysmal tachycardia and heart block. The authors state that caution must be exercised in interpreting the values for the circulation time in patients suspected of having heart failure in the presence of pulmonary emphysema or marked pulmonary fibrosis. Fever and anemia tend to increase the velocity of the flow of the blood. A slowing of the velocity of the blood was found in patients suffering from polycythemia or myxedema. The velocity of the blood was determined in seventy-eight patients with clinical manifestations of exophthalmic goiter. In sixty-eight patients who showed no evidence of heart failure the velocity of the blood was distinctly faster than normal, and in the ten with signs of cardiac failure the circulation time tended to be an arithmetical average of the two conditions.

Angina Pectoris and Aortic Valvular Disease—Laplace reviewed seventy-two cases of aortic valvular disease with especial reference to the relation between the incidence of angina pectoris and the height of the diastolic pressures. Angina pectoris occurred in 83 per cent of the cases in which the diastolic pressure was 80 mm of mercury or above, in 33.3 per cent of the cases in which it was between 79 and 40 mm and in 16.7 per cent of the cases in which it was below 40 mm. The fact that this syndrome did not occur most frequently in the latter group indicates that a low diastolic pressure is of relatively slight importance in the pathogenesis of angina pectoris. The author also studied the incidence of congestive failure but its increase at low diastolic levels was insufficient to account for the relatively greater decrease in the incidence of angina in the same group. These observations indicate that the appearance of angina pectoris in cases of aortic regurgitation cannot be attributed to an insufficiency of the coronary perfusion pressure during diastole. They support the view of Hochrein that the work of the heart is the most important factor in determining the volume of the coronary blood flow, that the myocardial circulation is relatively little affected by alterations in the diastolic pressure level and that cardiac systole does not significantly obstruct the coronary vessels.

Gonococcal Endocarditis—Newman reports a case of gonococcal endocarditis that developed in the course of a gonococcal bacteremia, following an induced abortion by tamponage and subsequently by curettage. This sepsis had run a chronic course of three and a half months preceding admission to the hospital. No valvular lesion was present on admission nor was there anything in the past history of the patient, by direct questioning or by symptomatology, to suggest antecedent valvular disease. During her stay in the hospital, which was markedly septic, an aortic and mitral insufficiency developed, confirmed by fluoroscopic examination and by an increase of pulse pressure under observation. The septic course went into spontaneous remission four months after onset, the patient having developed peripheral embolic phenomena, a focal glomerulonephritis then went on to recovery and was discharged with an aortic and mitral insufficiency.

Meningitis—De Sanctis and his associates investigated the sugar, lactic acid and cell count of the spinal fluid in various types of meningitis. The modification of Brahme and Brahmé of Clausen's method was used for the determination of lactic acid. Daily analyses of spinal fluid were made on a group of forty-four patients with meningitis throughout their stay in the hospital. The authors observed a rise in the lactic acid of the blood and of the spinal fluid in some cases of epilepsy, encephalitis, chorea and nephritic convulsions and in acute infections such as pneumonia and mastoiditis. In these conditions the

lactic acid of the spinal fluid is less than that of the blood and varies with that of the blood. In meningitis the lactic acid of the spinal fluid exceeds that of the blood and the authors believe that the increase in the latter is dependent on the increase observed in the spinal fluid. With clinical improvement the lactic acid of the spinal fluid approaches that of the blood. For the determination of pathologic states of the central nervous system, such as meningitis and abscess or tumor of the brain, a knowledge of the ratio of spinal fluid lactic acid over blood lactic acid is a practical diagnostic aid whenever this ratio exceeds 1. The fact that the lactic acid varies directly with the cell count supports the theory that the increased lactic acid of the spinal fluid in meningitis is a product of cellular metabolism. The authors further confirm this fact by their *in vitro* experiments on glycolysis in spinal fluid.

Cod Liver Oil Concentrate—Barnes divided forty-two rachitic infants into three groups of thirteen, fourteen and fifteen respectively, and gave them each 6, 12 and 18 drops, respectively, of a corn oil solution of a cod liver oil concentrate of such a potency that they received, according to the groups, 4,000 units of vitamin D and 10,000 units of vitamin A, 8,000 units of vitamin D and 20,000 units of vitamin A, and 12,000 units of vitamin D and 30,000 units of vitamin A. Healing was rapid in all cases and was borne out by the return of the blood calcium and phosphorus to normal within an average period of two weeks or less and a rapid increase in strength and activity on the part of the child. Roentgenograms showed rapid calcification, and this roentgen evidence paralleled the improvement in the blood picture. The medication was well taken and caused no dietary disturbances. The healing was due to the cod liver oil concentrate and not to a loss of weight or a stationary weight, as is shown by the progressive gain of the children. That it was not due to the effect of the rays of the sun was evident by the fact that patients with active rickets who showed no healing were continuously coming to the clinic up to the time the experiment was concluded. This cod liver oil concentrate retains its active antirachitic effectiveness as measured in rat units of vitamin D, and in the dosage levels studied, is remarkably effective in curing rickets in infants.

Phenolsulphonphthalein Test—Chapman and Halsted used the fractional method of estimating the elimination of phenolsulphonphthalein (15, 30, 60 and 120 minutes) in twenty normal subjects and a large number of patients with suspected renal disease. They found that in chronic interstitial nephritis the fractional test may show evidence of impaired renal function when the test, as usually done with hourly collections is interpreted as normal. This fractional test is quite as informative

as the urea clearance test and reflects the diminishing function in progressive kidney disease. Since it is easier to perform, it is the method of choice for routine clinical work.

Chemical Peculiarity of Pellagra Blood—About a year ago, Campbell noticed that the erythrocytes of pellagrous blood caused more rapid decolorization of iodine solutions than other human erythrocytes, whether normal or pathologic. After a series of experiments designed to test this observation he developed a technique that promises to be of value as a clinical laboratory test in the diagnosis of pellagra. The reagents used are a mixture of 3 volumes of 95 per cent ethyl alcohol and 4 volumes of ether and an accurately prepared compound solution of iodine. In preparing the color standards a 3 per cent potassium dichromate solution is made and from this the following dilutions should be made: 1/5, 1/10, 1/20, 1/40, 1/80, 1/120 and 1/240. These standards are placed in a series of test tubes of the same internal diameter. The procedure is as follows: Samples of 5 cc of normal or nonpellagrous (control) and of suspected pellagrous venous blood are withdrawn and quickly introduced into 15 cc centrifuge tubes containing 5 cc of liquid petrolatum. The time of collection of each specimen must be recorded. As each sample is collected, the tube is stoppered and shaken until the blood is defibrinated. The specimens are then allowed to stand from thirty to forty-five minutes after which they are again shaken and centrifuged at 1,000 revolutions per minute for five minutes. When the tubes are removed from the centrifuge three distinct layers may be distinguished: an upper layer of fibrin and oil, a middle layer of serum and a lower layer of erythrocytes, leukocytes and the like (the erythrocytic layer). If any sample has not been properly defibrinated, clots will be present in the lower layer. Now 1 cc samples of the erythrocytic layers are transferred by means of serum pipets to test tubes of the same diameter as those of the standards. Exactly one hour after taking the venous blood specimen, 5 cc of the alcohol ether mixture is added to the corresponding erythrocytic sample, and the tube is stoppered tightly. After the alcohol ether mixture has been added to all samples, they are allowed to stand for approximately six hours at room temperature (from 25 to 30°C). At the end of this time a 0.1 cc portion of the iodine solution is added in rapid succession to each tube by means of an accurate micropipet. This is mixed gently and the stoppers are replaced. As the mixtures stand there will be noted a gradual diminution of color in each tube but a greater decolorization in the pellagrous samples. Within three hours the extract of pellagrous blood may be completely decolorized while other samples are not. The most constant difference occurs after the tubes have stood about twelve hours. At this time the colors of the alcohol ether extracts should be compared with the potassium dichromate standards. The color range of these standards represents that of most samples which have stood twelve hours. If the color of the unknown matched that of a standard two shades lighter than the nonpellagrous sample, a mild condition of pellagra was apparently indicated. If it compared with a standard three shades lighter than the normal, a moderately developed condition of pellagra was considered to be present. If the unknown compared with or was lighter than the fourth tube from the nonpellagrous or normal standard, advanced severe pellagra existed. The author reached these conclusions by a study of more than 150 hospital and dispensary cases, including a variety of diseases, fifty of which were pellagrous.

Normal Blood in Pernicious Anemia—Murphy observed that intramuscular injections of the solution of liver extract, given to patients in relapse or whose condition was unsatisfactory because of complications, instigated a remission in each instance, as is to be expected with treatment by means of the ingestion of liver or of an actively potent substitute. The beneficial effects of intramuscular injections occurred sooner and more strikingly than with peroral treatment. Maintenance treatment, carried out by the same means in eighty-one instances for sufficiently long periods of time to allow analysis of the amount of solution needed, shows that an intramuscular injection of the amount of solution derived from 100 Gm of liver (generally 3 cc), at intervals varying from one to six weeks, has maintained all these patients in a satisfactory state of

health with a normal condition of the blood. Improvement in the symptoms generally considered to accompany spinal or peripheral nerve damage has occurred regularly and often strikingly, and progression of these disturbances has not occurred in any patient after the blood condition has become essentially normal. Relapse has not occurred in any patient continuing under observation and treatment. The anemia diet, but not including liver, as previously suggested for the patient with pernicious anemia, has been advised in each instance and a course of large daily doses of iron (ferric ammonium citrate) has generally been prescribed at some time during the course of treatment, in order to allow the hemoglobin level to keep equal with the course of the rapid red blood cell formation. This has been of distinct benefit in improving the physical condition of the patient. It has been possible with the use of the intramuscular treatment to maintain this group of patients in a better state of health and with a more satisfactory condition of the blood than was possible by means of treatment by mouth, the prolonged treatment has been more economical to the patient, and this method of administration of liver substance has usually been better liked.

Effect of Thyroidectomy in Heart Disease—Berlin outlines a new method for the treatment of chronic heart disease which consists in the total ablation of the normal thyroid in patients without clinical or pathologic evidence of thyroid toxicity. The anterior surface of the exposed portion of the gland is searched for atypically located parathyroids. A pyramidal lobe is always sought for and if found entirely removed. If the condition of the patient warrants the gland is totally removed in continuity. A careful search of the entire gland is made for adherent or embedded parathyroids which if found are reimplanted in the sternomastoid muscle in accordance with the technique adopted by Lahey in the operation of partial thyroid-

ectomy. To avoid insult to the laryngeal nerves by the accumulation of serum or the formation of a hematoma, drainage is instituted. Drains are made to pass through the sternomastoid muscle on each side. The skin is closed with Michel clips and a firm sterile gauze dressing is applied. The author emphasizes the necessity for total ablation of the gland in order to insure a persistently lowered metabolic rate.

Method for Reducing Fractures of Head of Tibia—Forrester states that in fractures occurring in and about the knee joint and involving the head of the tibia, he waits from a week to ten days for the swelling to subside and then under a general anesthetic, reduces the displaced fragments with his reconstructed redresseur (straightening instrument) placing the fixed wooden button on the inside or normal area and by manipulation with the handle of the instrument, producing forcible yet steady pressure over the fractured area with the other button. Following reduction, it is noticeable that the application of the cast does not change the position of the reduced fragments, indicating that the logical time to do this is from a week to ten days after fracture, at which time the organized deposit about the fracture helps to hold it following reduction. Stockinet is applied from the toes to above the knee as high on the thigh as possible, and a Bohler cast is molded over the entire limb from the thigh to the toes. In from seven to ten days after reduction and application of the cast and as soon as the pain has subsided, the author applies his knee joint hinges. The patient is instructed to manipulate the splint by flexing the joint increasingly each day, beginning with a flexion of 5 degrees on the first day, increasing it to 10 or 15 degrees on the following day, and so on until full flexion has been obtained. The patient should be instructed to extend the knee fully at night and every night, because if this is not done there may form a bony deposit in the anterior chamber of the knee that will lock it and limit full extension.

Treatment of Polycythemia—Falconer compared the results of venesection of the administration of phenylhydrazine hydrochloride by mouth and of irradiation over the spleen and the long bones in the treatment of polycythemia. The results indicate that venesection used as a means of reducing the red cells and hemoglobin in polycythemia, does not increase the reticulocyte count above normal limits. Irradiation over the spleen or the long bones in polycythemia does not stimulate the bone marrow as indicated by the reticulocyte count. Owing probably to its slow action in the reduction of the blood level the average daily reticulocyte count was lower than following venesection. In a patient with true polycythemia following the administration of 1.4 Gm of acetylphenylhydrazine the reticulocyte count rose promptly to 8 per cent and fell gradually to normal over a period of eighty-two days. The study suggests that venesection may be a useful adjunct to phenylhydrazine treatment by permitting much smaller doses of this drug to be efficient in maintaining an approximately normal blood level.

Test for Measuring Variability of Blood Pressure—Hines and Brown outline a test for measuring the variability of

blood pressure, which consists in placing the subject in a recumbent position for fifteen minutes or until the blood pressure has attained or approximated the basal level. In cases of hypertension, as long as forty-five minutes may be required. With the cuff placed on one arm, the opposite hand is placed in ice water having a temperature of from 4 to 5 C., the blood pressure is taken at the end of thirty seconds and again at the end of sixty seconds. The hand is removed from the ice water and readings are taken every two minutes until the blood pressure returns to its previous basal level. The highest reading obtained is recorded as a measure of the response. Except for a small group of patients with hypertension the blood pressure returns to the basal level within two minutes after the hand is removed from the ice water. This reaction is independent of any significant changes in the pulse rate. There is a response in both the systolic and the diastolic pressures but somewhat less and more variable in the latter. It is likely that the response to cold has purely a neurogenic reflex basis because of the speed of the reaction, which is too rapid for the intervention of any known hormone or chemical factor. A tourniquet producing stasis of the flow of blood in the arm that is immersed fails to inhibit the reaction. The authors observed 230 subjects: 69 normal, 41 with diseases other than of the vascular type, 26 with localized forms of vascular disease, 76 with hypertension and 18 without hypertension who seemed to be normal, except that they gave abnormal reactions. There was evidence to indicate that certain persons have a constitutional or biologic abnormality leading to the development of essential hypertension. Demonstration of this potentiality should be possible theoretically years before the onset of the clinical degrees of high blood pressure. Subjects can be grouped as those with minimal and those with excessive responses of the systemic blood pressure to sensory and psychic stimulation. There is some evidence that the so-called normal persons who exhibit this hyperactivity will eventually suffer from hypertension unless development of this condition is forestalled. At least 98 per cent of all patients suffering from essential hypertension exhibit excessive reaction to local cold. Patients exhibiting other diseases have normal or minimal reactions. The cold test is useful in determining the efficacy of therapeutic measures to control the vasomotor irritability.

Surgical Treatment of Angina Pectoris—Witte is of the opinion that operations on the cervical sympathetic trunk, even if they include the stellate ganglions, cannot interrupt all the pathways of cardiac pain. The upper thoracic sympathetic ganglions or their communicating branches, or the posterior roots of the corresponding spinal nerves, are the logical points at which to interrupt painful stimuli from the heart. These anatomic and physiologic premises have been put to the test in thirty-two cases. In each case in which the author has been sure of a successful interruption of these structures, angina pectoris has disappeared. Paravertebral alcohol injection is difficult technically because of the depth of the nerves and the small areas sclerosed by the alcohol. However, it is the safest method, and its results are far better than the old forms of cervical sympathectomy. The upper thoracic sympathetic ganglions have been resected in four cases with striking relief of pain on the operated side. However, the author believes that this is too severe an operation for the average patient suffering from angina pectoris and that the best surgical procedure consists of first attempting to block the thoracic sympathetic nerves with alcohol. The patients who fail to obtain satisfactory relief provided they are reasonably good surgical risks, can finally be subjected to section of the posterior spinal roots.

Chancroid—After having used the vaccine of Nicolle and Durand in his hospital service (more than 400 cases) and in a few private cases since 1927 with uniformly good results, Pardo-Castello concludes that vaccine therapy is indicated in all cases of bubo, phagedena and phimosis with inaccessible chancroids. In uncomplicated chancroid, local treatment by means of cauterization with pure phenol and dressings of iodoform powder is usually sufficient to bring about a rapid cure. In some cases electrodesiccation followed by iodoform dressings gives the best results. In the inflammatory cases with secondary infection, wet dressings of potassium permanganate or of copper sulphate 1:1,000 are indicated previous to cauterization. If the lesions fail to heal or if there is any tendency to spreading, vaccine therapy is indicated even in the absence of complications. Patients under treatment for chancroid should be kept ambulatory when possible.

Treatment of Vitiligo—In a case of leukoderma, Cohen instructed the patient to apply a 10 per cent alcoholic solution of oil of bergamot to all the affected areas twice a day. Ultra violet irradiation with the carbon arc lamp was applied to the face for from three to five minutes twice a week, and an intra venous injection of gold sodium thiosulphate (0.1 Gm.) was given once a week. Within two weeks the areas on the face had begun to coalesce. At each visit the hyperpigmented patches were seen encroaching on the depigmented spots, and in six weeks the face was completely free from any evidence of the disease. The patches on the thighs and abdomen were also lessened, but the improvement was not as rapid as it was on the face, which had received ultraviolet irradiation in addition to the oil of bergamot. The patient was treated for fourteen weeks, during which period she received a total of 14 Gm. of gold sodium thiosulphate. The other vitiliginous areas were treated by several ultraviolet irradiations with excellent results, but the patient discontinued treatment after her face was freed from the disfigurement. She was seen one year after the last treatment, the vitiliginous areas had not returned. Her face was completely free from any pigmentary disfigurement, and the patches on the thighs and abdomen were greatly improved.

Hemangio-Endothelioma of the Esophagus—Broders and his associates report a case of primary hemangio endothelioma of the esophagus in which the diagnosis was made during life. The patient was a woman aged 76, in whom six weeks before examination dysphagia and considerable substernal pain developed rather suddenly. Physical examination revealed nothing significant except that all the teeth were absent and dental plates were worn. Roentgenographic examination revealed an irregular obstruction in the lower part of the esophagus. Esophagosopic examination disclosed an infiltrating lesion invading the left anterior wall of the lower portion of the esophagus. The lumen of the esophagus was considerably reduced and a small amount of purulent secretion was observed.

exuding from the lesion, which contained a green-producing streptococcus when grown on blood agar plates. Microscopic examination of the tissue revealed an inflammatory process associated with colonies of an organism that appeared to be some form of *Streptothrix*. Esophagoscopy examination was made two days later and the tube, introduced into the lesion to a greater depth than before, encountered a foul necrotic mass. A number of small pieces of tissue removed for microscopic study presented the microscopic picture that was noted in those previously examined. The specimen contained the structure characteristic of hemangio-endothelioma. In a few areas of the specimen were groups of closely packed relatively small hyperchromatic round and oval neoplastic cells. For the most part however the specimen was made up of a network of small ill defined blood vessels and spaces lined with endothelial cells that were indistinguishable from those that were closely packed. The authors believe that the presence of these neoplastic vessels represents an attempt of the tumor cells to differentiate and therefore is an indication of lowering of the clinical malignant condition. Occasionally, mitotic figures appeared in both the solid and the vascular areas.

Effect of Morphine on Intestine.—Orr and Carlson studied the effect of morphine sulphate on the movements of the jejunum in dogs by means of kinographic tracings taken with a balloon in Thiry-Vella loops, through Ivy-Mann enterostomies of the upper jejunum and of the ileum through an ileostomy, and also its effect on the movements of the small intestine in human beings by means of tracings taken with a balloon through an ileostomy opening by observations of large hernias and by auscultation of both the normal and the pathologic abdomen. Morphine sulphate in ordinary doses gives an increase in tone, an increase in the amplitude of segmentation movements and an increase in the frequency and amplitude of peristaltic waves. Large doses stop peristalsis and decrease the tone but segmentation movements are little affected and may be somewhat increased. The duration of the effect of an average dose of morphine on the intestine is about six hours. This is true for both animals and man. Morphine stimulates the obstructed as well as the unobstructed intestine in animals as recorded by the kinograph and in man and animals as determined by auscultation. There appears to be no increase or decrease in response to morphine as death approaches. A single dose of morphine caused retention of the barium meal in the animal and in the human stomach. The emptying time was at least twice the normal. A marked delay in the emptying of the ileum in the dog was noted. Morphine evidently produces a spastic action on the sphincters which delays the progress of barium through the gastro-intestinal tract.

Lymphatic Drainage of Joints.—Kuhns attempted to find out the nature of the lymph canals of the joint in the lower extremity and their drainage and also the possible relationship of lymphatic drainage to arthritis. Injections of India ink were made directly into the joints of living young adult animals. Either ether anesthesia was given in order to prevent extravasation of the ink into peritubular structures. From this

study the author concludes that lymphatic canals are present as abundant small vessels in the tissues lining joint cavities. They are most numerous just beneath the endothelial cell layer of the synovial membrane. The lymphatic drainage of the joints in the lower extremity is through the so-called deep lymphatic canals to the popliteal, deep femoral and iliac lymph nodes. Inflammation in the synovial tissues results in a decreased ability on the part of the lymphatic canals to absorb material larger than of molecular size. An apparent obliteration of the lymphatic vessels occurs when the inflammatory process is sufficiently severe or long continued. With the subsidence of the inflammatory reaction the lymphatic canals are again seen in their usual size and distribution and absorption of particulate substances by the lymphatic vessels is observed. Persistent inflammation in synovial tissues is dependent to a certain extent on the failure of the lymphatic vessels to function.

Suture in Wound of Vena Cava.—Bigger and Wilkinson report a case of wound of the superior vena cava treated by suture and state that, when such a vessel is injured outside the pericardium, the signs and symptoms are those of massive intrathoracic hemorrhage, whereas, if the intrapericardial portion is injured, cardiac tamponade is apt to result. No case of repair of such a wound can be found in the literature. Because of this fact and the importance of recognizing the possibility of such a wound so as to make an incision that will give adequate exposure the authors report their case.

Electrocardiograms in Angina Pectoris.—Hamilton and Robertson present a case history and complete electrocardiographic observations of a patient during an attack of angina pectoris during the cessation of this attack and during a sudden and fatal second attack, the graph continuing through and after the patient's death. The diagnosis of angina pectoris was confirmed by necropsy. The cessation of the auricular function was noted early, changes then became evident in the ventricular complexes and the heart became extremely irritable; the patient finally dying of ventricular fibrillation. It was possible to hear the heart sounds with a stethoscope over the apex of the heart, for at least three minutes after the beginning of the ventricular fibrillation. A study of the electrocardiogram shows that cessation of the cardiac function is not simultaneous with clinical death but follows this. In comparing the process of the dying heart in this case with that of other reports the authors find that it is not identical in all cases. Cessation of function precedes chemical changes and until these changes take place it is possible by stimulation to get a return of cardiac function. This explains the beneficial effect of epinephrine injections after clinical death in a number of such cases reported. Clinical death does not coincide with chemical or physiologic death.

Oleothorax.—Ross gives a study of oleothorax based on twenty five cases. Indications for its use were persistent purulent

pleural effusion, ineffectual or obliterative pneumothorax, mobile mediastinum and bronchopleural fistula. He considers olive oil less irritating and more absorbable than liquid petrolatum, especially in empyemas. Sensitiveness of the pleura should be tested at the beginning by small amounts of oil. In his series, 60 per cent gave no reaction. Thirteen of the patients were improved, nine were unimproved (one of the nine left the sanatorium and so discontinued treatment early), one became worse and two died. In seven, or 58 per cent, of the empyema cases there was improvement. The author's general impression is that pleurothorax is not an easy method of treatment to manage and requires careful observation and experience but is of distinct value in some cases. He has found that warming the oil to body temperature and using an 18 gauge needle and a 20 cc syringe works well. After each 20 cc of oil is injected an equal amount of air should be aspirated and the intrapleural pressure can be determined occasionally by the manometer. When underlying fluid is being aspirated the patient should be placed in the sitting position and the needle should be inserted low. The intrapleural pressure has to be watched.

Increase in Toxicity of Neoarsphenamine—Morrell and Chapman found that 4 per cent solutions of neoarsphenamine, standing exposed to air for twenty minutes, increase in toxicity as much as 56 per cent, calculated on the basis of solutions five

minutes old. Evidence is presented that the increase in toxicity of solutions caused by their preparation and an exposure of fifteen minutes to air is about 107 per cent, calculated on the basis of protected solutions. These increases in the toxicity of neoarsphenamine solutions can be prevented by preparing and keeping them under a layer of white liquid petrolatum. Neoarsphenamine solutions thus protected show no increase in toxicity after standing under oil for one hour, and there is some evidence that no increase in toxicity occurs in two and a half hours. There is a slight decrease in the toxicity of neoarsphenamine solutions kept under oil. This decrease remains constant and is insignificant when compared to large increases shown by unprotected solutions. The alterations in the toxicity of unprotected solutions make it impossible to obtain accurate or consistent results if they are used in toxicity tests. Protected solutions yield consistent and reliable results.

Cyanide Poisoning—Turner and Hulpieu state that the method of administering a poison in divided doses, each of which is sublethal but which are given rapidly enough to produce an accumulative effect, appears to be more satisfactory than the customary method of giving single lethal doses. Their results with sodium thiosulphate and dihydroxyacetone are in full agreement with those of a number of investigators. The authors were unable to confirm the observations of Forst and others in regard to the value of dextrose as an antidote for cyanide poisoning. Their results in this respect are in agreement with those of Hynd, Heymans and Soenen and of Rentz who were unable to demonstrate beneficial effects of dextrose. Their experiments with asphyxia induced by the use of a mask and the experiments in which the lactic acid was determined gave results that would be expected if the main action of cyanide is to depress cellular respiration. The fact that cells in a condition of oxygen want can secure energy by the breakdown of glycogen to lactic acid but are unable to reverse the process combined with the appearance of asphyxial convulsions which are almost always produced in cyanide poisoning accounts for the rapid rise in blood lactic acid. During recovery from oxygen want the cells again regain their ability to convert lactic acid to dextrose or to glycogen, and consequently the lactic acid of the blood rapidly falls to normal, while the dextrose in the blood is more slowly reconverted to glycogen.

Effort Thrombosis—McGoogan and Simmons present a case of thrombosis of the veins of the upper extremity in a woman who had been well until her first pregnancy, following which she developed a chronic nephritis and was advised not to become pregnant. Six years later she became pregnant again and was admitted to the hospital one week before delivery during which time she was under intensive antitoxemic treat-

ment A classic cesarean section was performed under spinal anesthesia Salpingotomy was advised but refused She was delivered of a normal female child weighing 6 pounds (2,720 Gm) Her convalescence was uneventful except for a gradual fall of the blood pressure with diminution but not actual disappearance of the albuminuria On the day following her dismissal from the hospital, the fourteenth postoperative day, she noticed a feeling as if she were unable to swallow, then a swelling on the left side of the neck above the clavicle which spread to the left shoulder, accompanied by pain around the shoulder She then was unable to move her left arm, and the veins on the back of her left hand were distended There was discoloration and distention of the veins in the axilla, along the course of the long thoracic vessels, and some swelling and discoloration around the left shoulder The veins of the left upper extremity down to those over the dorsum of the hand were distended Palpation of the axilla was impossible because of pain The pulse was 146 and weak The heart sounds were similar to those heard in a case of pulmonary thrombosis The temperature was 99.6 F The swelling gradually descended down the left arm until the entire shoulder region arm, forearm and hand were edematous and cyanotic On the seventh day after the onset the pulse was slower and the patient felt better but she was unable to move the extremity The edema and cyanosis gradually disappeared and five weeks after the onset of the disturbance the patient was able to move the extremity somewhat and was allowed to get out of bed When she was up the edema and cyanosis returned to some degree and persisted for another month The cyanosis disappeared about this time but the swelling persisted for six months For the past ten months the patient has been able to do her own house work without difficulty The authors believe that thrombosis was due to the fact that the patient helped lift herself up in bed by holding on to the rods at the head of the bed Such a maneuver would of necessity entail abduction, extension and probably lateral rotation

Roentgen Pelvimetry—Thoms gives a modification of the grid method using the pelviscope which he describes The eye of the examiner occupies the position of the target of the X-ray tube and views the developed roentgenogram through a glass centimeter grid placed in the position formerly occupied by the superior strait of the patient The level of the superior strait for this latter purpose may be determined by means of the plumb bobs or entirely by calipers measuring from the sensitive film to the points of identification above He places directly on the sensitive film identification marks (iron washers) which mark the center of the roentgenogram under the target the point under the symphyseal which represents the point of contact of the lower arm of the calipers and the point under the posterior pelvic measurement which represents the point of contact of the lower arm of the calipers in this position The eyepiece of the observer must be in the same hori-

zontal plane as the center of the developed plate in the viewing box In other words, the conditions which obtain vertically in making the exposure are made horizontal for convenience When the developed roentgenogram is viewed, it becomes possible to trace the course of the superior strait directly on the glass grid with a wax pencil, this tracing represents the true superior strait It may then be traced directly on centimeter paper, which can be filed with the patient's chart The author states that the pelviscope method has one advantage over the centimeter grid method in that a tracing of the superior strait in its true proportions becomes available

Acute Bronchopulmonary Diphtheria—Toomey reports two cases of acute tracheobronchial diphtheria without laryngeal faucial or nasal symptoms Both occurred in young adult males, one of the fatal fulminating type, and one of intermediate virulence, with recovery following the employment of antidiphtheritic serum only in large dosage intramuscularly and intravenously, and insulin and dextrose to support the heart The obscure nature of the ailment, its rarity and the lack of common knowledge concerning it makes early diagnosis unlikely A rapidly developing toxemia of insidious onset, with pallor, bronchial obstruction cyanosis or other symptoms of impending circulatory collapse should, especially in the presence of abnormal auscultatory signs over the chest, lead to pseudomembrane in the bronchi being sought for by direct smear, by expulsion (induced coughing) and by roentgenography despite the absence of inflammation or fibroplastic exudate in the fauces, nasopharynx or larynx A large proportion of these cases will be recognized early by roentgenography rather than by cultural or bacterial inspection methods, owing to the negative aspect of the fauces, larynx and nasopharynx The prognosis is grave virtually fatal for fulminating cases, but, for those of moderate virulence, the prognosis is better than for laryngeal diphtheria of like virulence, provided a correct diagnosis is established within three or four days of onset A single massive dose of antidiphtheritic serum should be given immediately by intramuscular and intravenous injection, and the heart should be supported by absolute rest, insulin and suitable cardiac stimulants, both primarily and also during the period of delayed cardiac deterioration

Antidotes for Cyanide Poisoning—Draize states that according to results obtained in his laboratory, two of the various antidotes advocated to treat cyanide poisoning are effective A dose of from 3 to 4 mg of a hydrocyanic acid solution per kilogram of body weight is fatal for the rabbit when administered orally The intravenous injection of from 2 to 3 cc of a 2 per cent solution of sodium tetrathionate per kilogram of body weight is effective in saving rabbits having received orally three times the minimal lethal dose of hydrocyanic acid The sodium tetrathionate solution is administered with the onset of the first symptoms of cyanide poisoning Rabbits tolerate three times the therapeutic quantity of sodium tetrathionate without exhibiting any toxic effects Methylene blue administered intravenously in the form of a 1 per cent aqueous solution does not afford as much protection Rabbits receiving more than two times the minimal lethal dose could not be saved The intravenous injection of quantities in excess of 25 cc of a 1 per cent solution of methylene blue was injurious to the rabbit In the trial of sodium tetrathionate in

carbon monoxide poisoning, rabbits were gassed to a point from which recovery was impossible without treatment. Sodium tetrathionate was more effective than methylene blue in reviving the poisoned animals.

Orris Powder in Meniere's Disease—Randall reports a case which, he believes, establishes the relationship of orris allergy as an etiologic factor in Meniere's disease. The patient has had periodic attacks of intense vertigo, tinnitus, nausea and vomiting for the past fourteen years. Headaches usually follow these attacks lasting for several hours. The nasal sinuses have been explored several times without relief. Family history is negative as to any suggestion of allergy. The patient gives a history of having had urticaria and hives. He states that attendance at theaters, dances and crowded places seems to provoke attacks. He states that he has never had a discharge from the ear. Roentgenograms show no pathologic changes in the sinuses or lungs. Sputum, Wassermann, genital urinary, urine and blood tests were all normal. Intradermal and epidermal food tests were negative. House dust was plus two and orris root plus four. The author used 0.02 cc of a 1:500 dilution of orris. Severe headache, nausea and vomiting occurred, and the patient had to be placed in a reclining position to prevent falling. This condition lasted about six hours. The patient was given daily doses of weak solutions of orris until a tolerance for a 1:500 solution was established. He now can tolerate as much as 0.05 cc of 1:100 solution. He feels much improved physically and mentally and does not have the attacks when he attends shows or dances and when he visits barber shops. He has been taught the use of the extract and gives himself intradermal injections whenever he needs them.

Occurrence of Sex Linked Variations in Twins C. E. Kellett—p. 269

Variation in Hemoglobin Level—Mackay describes the usual variations in hemoglobin level during the first year of life relating to their causal factors. Some of the conclusions are tentative. The high hemoglobin level of the newborn infant is known to be related to the low oxygen tension of the blood of the fetus in utero and its consequent need of a relatively greater amount of hemoglobin. After birth there is a fairly rapid destruction of red cells, and the more fragile immature cells which are present in greater proportion in the blood of immature infants are destroyed early. Hence there is a rapid fall in hemoglobin in the first week of life, greater in small than in large infants. This destruction causes a further increase in blood bilirubin and may give rise to an icteric tinge of the skin (physiologic jaundice). During this stage of physiologic blood destruction the production of red cells is presumably decreased, as shown by the small number of reticulocytes in the blood of normal infants between the ages of 1 and 4 weeks. The drop in the red cells continues until about the third month of life. The evidence available again points to an increase in the production of red cells between the ages of 5 and 8 weeks though it does not usually exceed destruction till the third or fourth month. Iron derived from hemolysis of red cells in the early weeks of life augments the original store present in the liver and spleen at birth and is utilized during the period of a rising hemoglobin level, between the third and sixth months of life. This store, however, quickly becomes depleted especially in infants whose rate of growth has been rapid, and consequent iron deficiency often retards the rise and usually causes a slow drop in hemoglobin level after the sixth month of life. Toward the end of the first year of life, a slow spontaneous rise in hemoglobin level may again occur, resulting from increased iron intake due to a mixed diet.

Treatment of Lupus—Dalsgaard describes an ambulatory treatment of lupus in which the patch is carefully cleansed with oil and ether to free it from all scales and crusts, so that the individual nodules and cicatrizations stand out clearly. Then follows a diathermy treatment, "spark painting." In this method the active electrode, a spatula about 3 mm wide (the patient holds the inactive one in his hand), is applied to the affected area so as to produce a shower of "microscopic" sparks between it and the electrode, giving the patch the appearance of having been painted with a diluted silver nitrate solution. When ulceration is present, the electrode is applied more deeply and the undermined margins in particular are carefully treated. This treatment can be borne by the patient without narcotics and anesthetics, and it should be repeated when the reaction following the previous treatment subsides and when the progress made can be gauged. On alternate days the author exposes the patient to the sun lamp at the shortest distance that can be borne painlessly. The first exposure is given immediately after the first diathermy treatment, which lasts for half an hour, this being increased to one hour at subsequent treatments. The affected part turns a flaming red immediately after this treat-

ment The sore is then bandaged and a neutral ointment applied The patient is instructed to take foods rich in vitamins and poor in animal albumin, two viosterol tablets and nine calcium tablets of 1 Gm each The viosterol may be replaced by cod liver oil

- *Pathologic Diagnosis of Female Gonorrhea W N Mascall—p 233

Cultivation of Bacteria-Free Vaccinia Virus—In Stevenson and Butler's technic, fertile eggs are used after an incubation period of ten or eleven days The air sac is marked off and an area chosen and marked over what appears to be, by transmitted light the membrane of the embryo in such a position as to be well within the shadowed portion but yet away from the darkest area The egg is placed on a stand so that the air sac end is submerged in a water bath at from 38 to 40 C The shell over the chosen area is rubbed with alcohol and allowed to dry Disinfection of the shell with tincture of iodine can be carried out with safety All instruments are dipped in alcohol and flamed With the sharp point of scissors or scalpel a small hole is drilled in the shell, damage to the shell membrane being avoided If the shell membrane is not perforated during this procedure it is incised, but no attempt is made to damage the chorion by pricking in the manner advised by Woodruff and Goodpasture, for the authors found that death of the embryo may be caused in this way The inoculum is drawn up into a sterile fine capillary pipet and a column of about 1 to 1½ inches injected below the shell membrane obliquely on to the surface of the chorio allantoic membrane when often it may be noticed that the movements of the embryo actually suck in any of the inoculum that may be left at the margin of the hole The shell opening is closed with melted hard petrolatum—sterile and not too hot, and near to the point of solidification The eggs are dried marked with identification numbers and dates returned to the incubator, turned morning and evening and allowed to cool off every day for fifteen minutes Incubation is continued for four days, after which the eggs are opened the upper third to half of the egg toward the more pointed end is dipped in alcohol and flamed and the shell is opened aseptically in that area, the chorio-allantoic membrane is incised with scissors and the contents within that membrane may drop out or be drawn out with forceps leaving as a rule the chorio allantoic membrane attached within the shell from which it can be separated with ease So far as the authors experiments indicate and as Woodruff Goodpasture and Buddingh hoped a vaccine may be produced at little expense absolutely free from contaminating micro-organisms apparently capable of producing on the rabbit lesions comparable to those produced by calf vaccine and so far as observed non-hemorrhagic The chick membrane virus retains its potency at least two months in glycerin if kept below 0 C The experience of the authors is that, unless interfered with deliberately chicks usually hatch out from the inoculated eggs at maturity, and healthy chicks result Examination of the membranes left in some of the hatched egg shells show that the membranes really were infected—in some cases heavily so Actually, from twenty-one inoculated eggs permitted to mature twenty-one chicks have hatched out Two died subsequently but it should be noted that they were reared under necessarily artificial conditions This experience contrasts with the observations of Woodruff Goodpasture and Buddingh who state that infected chick embryos usually die on the fourth day after inoculation This may be due to the difference in the strains of virus employed—in the authors case dermal in their case neuro-

testicular They add that, when eggs are opened on the fourth day after inoculation, occasionally a dead embryo has been found, presumably as a result of the operation or from the infection, for example, out of forty-nine inoculated eggs that were opened, two contained dead embryos

Adolescent Hypertension—Hoyle describes a case of adolescent hypertension in which a pressor substance, related to epinephrine physiologically was excreted in the urine They suggest that the case may be an example of high blood pressure resulting from an acquired or inborn error of metabolism

Diagnosis of Female Gonorrhea—Mascall analyzes the results of investigations, performed on the first attendance of the patient in 500 consecutive cases of gonorrhea definitely diagnosed by means of (1) smears, (2) cultures, and (3) the gonococcus complement fixation test of the blood serum These methods were used as a routine and no case was labeled as gonorrhea unless or until pathologic tests proved the presence of the gonococcus, clinical observations alone were considered insufficient Cultures produced the highest number of positive results (66.8 per cent) The value of the gonococcus complement fixation test, as shown by this series is second (58.6 per cent positive results) but the corrected figure, 79.6 per cent when the latest technic is used, places this test first It has a definite place among the diagnostic methods of gonorrhea, but the clinical history and condition must be closely considered when the result of the reaction is being interpreted In many cases it is indispensable, as 142 cases (20.8 per cent) were discovered which otherwise would not have had their true nature revealed Smears alone, even when stained with Gram's stain give poor results (45.4 per cent), as no less than 54.6 per cent are overlooked This figure is even greater if methylene blue is the only stain employed Whenever possible the three methods should be combined The results from one method alone may not be dependable In gonococcal infections, errors in diagnosis may lead to such serious consequences both for the patient and for the medical attendant, and the underlying cause of the trouble is frequently so elusive that every possible method of diagnosis should be used that the proportion of mistakes may be reduced to a minimum

Comparative Value of Drugs in Angina Pectoris—Evans and Hoyle observed a series of ninety patients with angina pectoris of effort over a period of two and a half years with especial reference to the comparative value of certain drugs used in continuous treatment Syphilitic angina pectoris was excluded and coronary thrombosis was considered only as a complication Each patient attended fortnightly, and the various drugs were administered over periods of from two to four weeks or longer In this way their effect on the frequency and severity of attacks could be compared As a control in each case a patient receiving placebo treatment was regularly substituted for an active drug The following drugs were tested sodium nitrate mannitol hexanitrate erythrol tetranitrate potassium iodide phenobarbital, chloral morphine papaverine, acetylphenetidm theobromine sodium salicylate theophylline ethylenediamine belladonna digitalis licarnol and harmol With one exception

the results show that a measure of improvement appears to result from every remedy tried, and at least as great an improvement as during placebo treatment. This universal efficacy can be explained only by natural variations in the severity of the symptoms, which give a spurious value to each remedy. There was some reason to think that chloral morphine, papaverine and acetphenetidin had a trifling influence in controlling the group incidence and severity of attacks. If, as the authors are convinced, none of these remedies are capable of lessening the frequency or severity of anginal attacks, there is all the greater need for a study of the application of those general measures known to control them and to promote the wider use of vasodilators, such as glyceryl trinitrate which are so often successful in the palliative treatment or even in the prevention of particular attacks.

Effect of Yeast and Wheat Embryo in Anemias — Ungley found that, in idiopathic hypochromic anemias with or without achlorhydria and whether or not the diet has been grossly defective, no effect on hemoglobin regeneration has followed the administration of massive doses of preparations of yeast or wheat germ. The experiments of Parsons suggest that yeast as well as iron may be indicated in the nutritional hypochromic anemias of pregnancy. In two patients with atypical pernicious anemia showing an incomplete defect in the secretion of hydrochloric acid combined with a gross dietary deficiency and associated in one case with dysphagia of the Plummer-Vinson type the administration of preparations of wheat germ and autolyzed yeast was followed by a hematopoietic response. Of ten cases of classic pernicious anemia treated with preparations of yeast and wheat germ seven showed a response and three failed to respond. Wheat germ gave an uncertain positive result in one case and negative results in two others. Autolyzed yeast or an extract derived from autolyzed yeast gave positive results of a greater or lesser degree in six of seven cases. One patient who failed to respond to autolyzed yeast failed also to respond to dried brewers' yeast. In classic pernicious anemia and in two cases of atypical pernicious anemia, the responses were usually less in degree than those obtained from autolyzed yeast in certain megalocytic anemias without achlorhydria. From the therapeutic point of view, the variable and usually subnormal results obtained with doses as large as can be tolerated indicated that none of the preparations used are satisfactory substitutes for liver in the relapse stage of pernicious anemia. On the other hand, the responses so far obtained from a 65 per cent alcoholic extract of autolyzed yeast suggest that an inexpensive product suitable for the treatment of pernicious anemia may yet be obtained from yeast. The author discusses the possibility that preparations of yeast may owe their potency in pernicious anemia to (1) the extrinsic factor, (2) a breakdown product of the extrinsic factor perhaps resulting from the interaction of this substance with an enzyme liberated during the autolysis of yeast, or (3) a substance resembling the liver active principle.

Acid-Base Equilibrium of Blood in Epilepsy — McLaughlin and Hurst studied the acid-base equilibrium of the blood in epilepsy, estimating the measurements of the blood pH , the alkali reserve and lactic acid. The results suggest that in the interval period between fits 1. Variations in the alkali reserve and lactic acid are usually within normal limits but those of the pH extend to a range slightly above normal. 2. The average concentration of lactic acid is normal. The average alkali reserve and pH values tend to be slightly above normal. The averages of the results obtained for the alkali reserve and pH during the two-hour period preceding the fit show no significant difference from those of the interval period. Results obtained from samples of blood of individual patients before, during and after seizures lead to the following conclusions: 1. There is a fall in the alkali reserve during and for varying periods after the fit, this fall being accounted for by the accumulation of lactic acid in the blood. A decrease in the lactic acid during recovery is accompanied by an increase in the alkali reserve. 2. The blood pH falls during the fit, owing first to apnea during the tonic stage and then to the production of lactic acid during the clonic stage. Recovery to the normal pH is of more rapid occurrence than is the case with normal persons after exercise.

Elimination of Neutral Red by Gastric Mucosa — Clinical Value — Method — J. Held — p. 827

Elimination of Neutral Red by Gastric Mucosa — Held states that the chromoscopic test based on the power of the gastric mucosa to eliminate neutral red injected into the muscle, has a great value in the differential diagnosis and prognosis of gastric lesions. On the basis of 160 chromoscopic tests ascertained with repeated examinations of the gastric contents after the effluent test meal, he concludes that the normal gastric mucosa eliminates the dye in from twelve to twenty-five minutes after injection. In hyperchlorhydria the elimination is accelerated (from four to fourteen minutes), while in hypochlorhydria it is retarded (from twenty-six to forty minutes). Although elimination is more rapid in hyperchlorhydria and less rapid in hypochlorhydria, there is no parallelism between the degree of acidity and the speed of elimination of the dye. In elimination of the dye by the kidney is impeded owing to renal disease, there is a compensatory acceleration of the elimination by the gastric mucosa, independent of the gastric acidity. In gastritis the elimination of neutral red is retarded if the gastric acidity is normal. The quantity of mucus influences the retardation aside from any glandular lesion. The elimination of the dye is increased in gastric or duodenal ulcer as in other conditions evolving with hyperchlorhydria. The chromoscopic test is above all useful for the diagnosis of conditions of gastric hyposecretion; the elimination is greatly retarded or lacking in achlorhydria due to organic lesions of the gastric mucosa, while it is not affected in psychic achlorhydria. The chromoscopic test is superior to the histamine test for determining the secretory function of the gastric mucosa in achlorhydria. In cases in which neutral red is not eliminated the histamine test is likewise negative whereas occasionally when the histamine test is negative the mucosa retains the power of eliminating the dye. The injection of histamine simultaneously with neutral red hastens the elimination of the dye by the gastric mucosa, and in certain cases with a negative chromoscopic test it causes the dye to appear in the stomach; this represents the final effort of the gastric mucosa. The diagnosis of a permanent gastric lesion cannot be made after a single chromoscopic test; it requires periodically repeated tests. In eleven cases of cancer of the stomach the chromoscopic test was negative six times, mostly in cases in which the cancer was localized in the pyloric region; in cancer limited to the body of the stomach the power of eliminating the dye is often retained rather long. In doubtful cases, progressively deficient elimination of the dye favors cancer and increasing rapidity of elimination militates against it. In all cases of pernicious anemia there was total achylia and the chromoscopic test associated with histamine was negative, indicating atrophy of the gastric mucosa.

Santonin Test of Antitoxic Function of Liver — A. Moukhtar and Hadidje Djévat — p. 1501

Santonin Test of Antitoxic Function of Liver — Moukhtar and Djévat test the antitoxic function of the liver by administering santonin and studying its elimination in the urine in the form of oxsantonin. The fasting patient is given 0.02 Gm. of santonin orally and thereafter the urine is collected every hour for nine hours. Three cubic centimeters of urine from each specimen is put in test tubes and to each is added 2 cc. of a solution of sodium hydroxide diluted with equal parts of water. This causes the oxsantonin, which is present in the urine and which is yellow, to turn red. Each tube is compared with a set of six graduated standards prepared with eosin. The preparation of the standards is described by the author. In normal persons the elimination of the oxsantonin starts at the end of one hour and increases progressively to attain its maximum toward the fourth hour. At this hour the concentra-

ion usually reaches the second or at most the third degree, the weakest concentration being represented by the first degree. Thereafter the concentration diminishes steadily to the seventh or ninth hour. In persons with hepatic disease the curve assumes different characteristic forms. Often the elimination attains its maximum more rapidly than normal and this concentration is maintained with slight oscillations for many hours (from nine to fourteen). In other cases the elimination of the oxy-santonin is irregular, after reaching a high concentration it drops suddenly to a low concentration, only to return again to a still higher degree than previously. These two modifications must be considered due to disturbances of the hepatic function. Retarded oxy-santonin elimination in patients with normal hepatic function occurs only in rare cases of retarded absorption of santonin. Weak or abundant elimination is not encountered in normal patients. The patient should drink a little water during the test, but not more than half a glass. In patients with nephritis this test is not always reliable. The authors have employed the test in 250 cases. Sometimes it was the only one that furnished a positive result in manifest hepatic disease. Repeated at intervals, it gives important prognostic indications.

Disinfection of Skin with Malachite Green.—Fiorini tested the relative merits of malachite green as a disinfectant on the skin and in culture and found that it had a strong bactericidal effect. Since malachite green shows bactericidal power in a simple saturated aqueous solution, the disinfecting power of alcoholic solutions must be due to the aniline dye. Malachite green dissolved in high grade alcohol at a concentration equal to that of tincture of iodine has a disinfecting power slightly less than that of tincture of iodine. The bactericidal power of solutions of malachite green grows with the increase of concentration of the dye and, up to a certain limit, with the diminution of the grade of the alcohol. The solution of malachite green best adapted to the skin of surgical patients (greatest bactericidal power and least irritating action) has a concentration of not less than 10 per cent in 40 per cent alcohol. In all the author's patients, after disinfection with malachite green as well as with tincture of iodine, the isolated germs responded negatively to Dreyer's test and thus were not capable of causing suppuration. In preoperative disinfection with malachite green, the cicatrization of the wound is facilitated by the elimination of all irritative factors usually observed after application of tincture of iodine. In the disinfection of very sensitive parts, such as the external genitalia a solution of malachite green with a low degree of alcohol prevents any disturbing irritation.

Indican of Blood in Tumors of Uterus and Ovary.—Salvini examined thirty-five patients, twenty-four of whom had fibromas of the uterus, ten ovarian cystic tumors and one both uterine fibromas and ovarian cysts. Examination of the urine of all patients previous to surgical intervention was constantly negative for indican. The author found that the rate of indicanemia increased after operation for tumors of the uterus and of the ovary. In hyperindicanemia much importance

has been attributed to a deficient renal excretory function even when clinical signs of renal disease were not manifest. Hyperindicanemia in uterine and ovarian tumors might be ascribed to a functional deficiency of the liver, particularly to a deficiency in the elaboration of glucuronic acid. The author maintains that a high degree of indican found before operation in the blood of patients having tumors of the uterus and of the ovary is due to insufficient renal function. He states that in these patients the higher amount of indican in the blood during the first few days after operation results from the renal insufficiency and from the intestinal paresis existing in all cases and tending to increase the putrefactive processes of the intestine. The examinations made during the last days of convalescence of the patients showed a steady diminution of the indicanemia. If it is admitted that hyperindicanemia in tumors of the uterus and ovary is due to renal functional insufficiency, it must also be acknowledged that, with the removal of the neoplasm, the influence exercised by it on the kidney ceases. In all cases the rate of indican steadily diminished after operation until it gradually disappeared. In determination of urinary indican the author always found normal values ranging from 10 to 20 mg per thousand cubic centimeters. The values of indicanemia never ran a parallel course in the sense that a hyperindicanemia corresponded to a hyperindicanuria. The author concludes that hyperindicanemia is indicative of deficient renal function and corresponds to a diminution in the amount of indican in the urine.

Acute and Subacute Neuromyelitis. Case. A. Austregesilo—p. 640
Syphilis of the Sclera. Case. W. Belfort Mattos—p. 643

New Serologic Variety of Shigella Dysenteriae.—De Assis states that he isolated an organism with some of the characteristics of Shigella ambigua from a specimen of feces of a patient suffering from acute febrile dysentery. It was a gram-negative, rod shaped, nonmotile bacillus which acidified dextrose, produced indole and sulphuric acid, and was inactive in lactose and mannite. However, it did not cause agglutination of Shiga, Flexner-Hess, Kruse-Sonne and Schmitz typical dysenteric antisera. That the organism was not a nonagglutinant type of Shigella ambigua was proved by the fact that the blood serum of rabbits inoculated with it had a high agglutinating power for the respective antigen germ. A comparative study of the typical Shigella ambigua and the isolated bacillus gave the following results. The newly found organism invariably acidified without forming gas, galactose, sorbitol, rhamnose and glycerin, all of which are not made acid by Shigella ambigua. On the other hand, Shigella ambigua acidified adonitol and sucrose, which are not acidified by the new organism. When the new organism was added to bromo-cresol-purple milk it proved to be inactive, except for producing a slight initial acidification of the milk. When Shigella ambigua was added to the same milk there was an intense late alkalization. The new bacillus has been compared only with Shigella ambigua and not with other types of Shigella dysenteriae. However, the serologic differences of the organism are so marked that the author considers it a new and entirely independent subgroup of the Shigella ambigua group not previously reported. The author proposes to designate the new organism as the Caxambu variety of Shigella ambigua, because the feces from which the organism was isolated came from a woman who lived in Caxambu, Minas.

Volkman's Contracture Treated by Periarthral Sympathectomy.—Landivar and Leoniparraguirre report the case of a woman aged 21 who suffered a fracture of the distal end of the radius of the right arm with the formation of a hematoma and total backward displacement of the radial epiphysis. Two

days later and while some attempts to reduce the fracture were being made, slight symptoms of Volkmann's contracture were observed. The consolidation of the fractured bone was obtained. Four months after the fracture had occurred, the patient showed a typical Volkmann contracture of the hands and fingers with retraction of the flexor and pronator muscles. All bloodless and orthopedic treatments failed. Humeral arteriotomy (for a length of 10 cm) was followed by the complete disappearance of the contracture. The patient obtained complete functional recovery, and the appearance of the hand and arm is now normal, two years after the operation.

Necrosis in Intracapsular Fractures of Neck of Femur.—Arce and Introzzi state that partial or total necrosis of the femoral epiphysis is a grave complication of transcervical and subcapital fractures. Early diagnosis and treatment of this complication are important to prevent the development of deforming arthropathy followed by invalidism. It is advisable to perform a roentgen examination of transcervical and subcapital fractures every two weeks after the fracture has been reduced and while the limb is immobilized in order to detect, as soon as possible, the appearance of necrosis. In necrosis the implantation of an apertosteal graft from the fibula into the neck, followed by a period of prolonged rest, gives satisfactory results. The period of rest should not be discontinued until the roentgen examination shows that restitution of the structure of the femoral epiphysis has taken place. In cases in which necrosis has advanced so far as to produce a grave arthropathy, Whitman's operation is indicated. This operation, however, should not be performed as long as the mobilization of calcium salts, characteristic of these pathologic conditions of the femur, is taking place. The myelosis observed in cases of necrosis complicating femoral fractures should not be considered to be caused by an irritating action of the graft on the bone but rather as a manifestation of intense disturbances of the local metabolism of nutrition of the bone involved. That the graft is not the cause of myelosis in these cases is proved by the fact that myelosis has been reported in various cases of the complication, whether a graft has been used or not and that similar myelotic changes appeared in certain points of the bone remote from the seat of the implantation in cases in which a graft was used. The authors report a case.

Effect of Gastric Resection on Bacteriology of Intestine.—Hertel and Sartorius studied the bacterial content of the small intestine in dogs after partial gastric resection by means of fistulas performed at various levels. They observed in the upper and middle portions of the intestine a marked increase in the number of the bacteria as well as a qualitative change, namely, an invasion by the organisms from the large intestine.

The change in the bacterial count seemed to depend to a certain extent on the nature of the nourishment and the acid phase of secretion produced by it. The authors made determinations of indole and of iodine binding aromatic products of decomposition and of acids. Constant differences, as compared with normal control animals, were obtained with indole determinations and to a less extent with indican, which seemed to run a parallel course with the former. An exclusive meat diet gave the highest indole content, especially after the second Billroth method of resection. A diet of milk, whey and especially that of sour milk produced insignificant amounts of indole. An attempt was made to correlate these observations with postoperative disturbances after a partial gastric resection such as dyspepsia, enteritis, anemia and the effect on the general state. Fermentation tests with chyme showed that even in the upper segments of the intestine there developed fermentative processes and decomposition of the character one sees in dyspepsia. This condition may cause an enteritis, which in its turn may cause auto-intoxication. The postoperative digestive disturbances may lead to secondary and even to pernicious anemia. The mild neurasthenic disturbances observed after resections have their foundation in organic alterations.

Pyloric Glands and Secretion of Gastric Juice.—Straaten states that in his experiments sham feedings failed to evoke high acid values in dogs with esophageal fistula when the segment of the stomach containing the pyloric glands was resected. When the pylorus was left but the rest of the stomach containing pyloric glands was removed, low acid values resulted from sham feedings. After a considerable time, however, high acidity could be provoked by sham feedings. It was only after a considerable lapse of time after the resection that sham feedings were capable of inducing low acid values when the pylorus and the portion containing pyloric glands were resected. The author concludes that the so-called first or psychic phase of gastric secretion is capable of producing high acid values only when some of the pyloric glands have been retained. He further concludes that the gastric segment containing the pyloric glands is capable of stimulating gastric secretion not only through mechanical and chemical stimuli, as formerly believed, but through psychic influences as well. The latter is a reflex phenomenon resulting in the secretion of a hormone which is transported by the blood to the fundal glands. These experiments justify partial gastric resection as therapy for the peptic ulcer especially if one accepts the role of the psychic secretion in the genesis of the ulcer.

Delayed Blood Coagulability in Obstructive Jaundice.—Barlik ligated the common bile duct in rabbits and found that this was followed in a few days by jaundice and delayed blood clotting. The plasma of such an animal was found to possess antithrombin, antiprotease and anticomplement properties. Cholemic serum when heated to 56° C was found to possess greater antithrombin property than similarly treated normal serum. At 70° C this antiprotease property was lost. The activity of prothrombin was found to be delayed in cholemic plasma. The author was able to increase the coagulability of the cholemic blood and plasma by acidifying the blood, through addition of chloroform or of carbon dioxide. He concludes that delayed blood clotting in experimental obstructive jaundice is due to increase in the blood content of antiprotease.

Tolerance of Nurslings for Crystallized Vitamin C.—After calling attention to the great significance of vitamin C in the feeding of nurslings, Kramar shows that normal nurslings

usually tolerate fruit juices well enough so that they receive sufficient amounts of vitamin C. In certain nutritional disturbances, however, the adequate provision with vitamin C is often difficult, and for this reason the author welcomes the fact that vitamin C is obtainable in pure form. He studied the efficacy of the pure vitamin in healthy and sick nurslings and in premature infants. He found that healthy nurslings tolerate from 25 to 50 mg daily, that new-born infants tolerate from 20 to 25 mg, and that premature infants can safely be given 15 mg. Febrile disturbances do not seem to inhibit the tolerance for the pure vitamin. Moreover, medication with the vitamin causes no gastro intestinal disturbances, and after this had been determined the vitamin was administered to nurslings with intestinal disturbances. The author gained the impression that the vitamin had a favorable influence on the development of premature infants and also that it played a significant part in the water metabolism.

Allergic Manifestations Caused by Coffee—Gutmann discusses the allergic manifestations caused by coffee. He describes the various methods of preparing coffee and estimates the caffeine contents of the different coffee extracts. He points out that, although small doses of pure caffeine produce palpitation of the heart, tremor, sweating, anxiety, nausea and diarrhea, coffee, or several cups of tea or of cocoa with a comparatively higher caffeine content and with theobromine, may be well tolerated. He ascribes this to the fact that in different stimulants the various xanthines are combined with different chemical substances. Caffeine for instance is combined with the tannic acid of coffee, which under the influence of hot water is split into caffeic acid and quinic acid. Moreover, the stimulating action of coffee is not solely dependent on the caffeine but also on the roasting products, which present a mixture of various chemical substances, such as furfural, pyridine and ammonia and also coffee oil, which is supposed to be the carrier of the aroma. In discussing the allergic action of coffee, the author differentiates susceptibility to caffeine from susceptibility to coffee as such. Allergic manifestations that develop after drinking coffee are itching, neurodermatitis, urticaria, Quincke's edema with particular involvement of the face, intestinal spasms with chronic constipation or, in other patients, diarrhea, also rhinitis, asthmatic disturbances, biliary colics and migraine. The author tested various types of coffee on persons who responded with such allergic manifestations. The coffee that was tolerated by the greatest number of "coffee susceptible" persons was one from which many roasting products, such as aldehyde, furfural, methyl alcohol, acetone, acetic acid, pyridine and ammonia, had been removed, while most of the aromatic substances had been retained. In the case of this coffee the greater tolerability is the result of the reduction of allergens, however, the better tolerance for caffeine-free coffee compared to ordinary coffee, which is likewise noticeable in many allergic persons, is ascribable to the fact that caffeine makes the patient more susceptible to allergic influences.

Results with Blood Transfusions—Schürer-Waldheim states that in the Graz clinic more than 500 blood transfusions were performed in the last four years with two fatal results due to faulty grouping of the donor. The method of selecting professional donors in their clinic included a general physical examination with particular attention to syphilis, malaria and gonorrhea. A Wassermann blood test was made every six weeks. To prevent fraud each certificate of health was accom-

panied by the photograph of the donor. The grouping is repeated before the transfusion. The donors are reexamined every six weeks and are not used oftener than once during that period. Some of the donors were used as often as twenty-five times without any harm to them. Blood grouping by means of the "hemotest" was not infallible and for that reason Oehlecker's biologic test was carried out at every transfusion. Blood transfusions proved strikingly effective in the control of acute hemorrhage of capillary or parenchymatous nature. Surgical intervention is necessary when bleeding comes from fairly large arteries. Spontaneous hemorrhage into the intestine, the genito urinary tract or the pulmonary tissue was effectively arrested by transfusions. In hemophilic patients, blood transfusion combined with hypodermic injections of sodium citrate had a favorable effect on the control of bleeding. Encouraging results were obtained by the use of massive and repeated transfusions in the treatment of the tendency to bleeding in patients having long standing icterus. In chronic anemia resulting from repeated hemorrhages, transfusions of smaller amounts of from 200 to 300 cc of blood favorably influenced the blood picture and the stypic properties of the blood. The cachectic state of patients with a malignant condition was favorably influenced by blood transfusions without, however, any effect on the rate of growth of the tumor. Transfusion was effective in combating postoperative shock, provided other and undetected causes did not operate at the same time, such as edema of the brain tissue, fat or air embolism, or a bleeding vessel. The method is applicable with good results in delayed convalescence, provided the function of the kidneys is unimpaired. Blood transfusion is absolutely contraindicated if the function of the kidneys is impaired. The results in suppurative conditions were not encouraging, but they can perhaps be improved by earlier, massive and repeated transfusions. Good results were observed in burns, and only transient improvement in diseases of the blood.

Pylorospasm of Nurslings—According to Boecker, the older anatomic concept of the so-called pyloric hypertrophic stenosis of infants was based chiefly on postmortem evidence. The pyloric tumor was found to be the result of hypertrophy of the circular fibers of the pyloric musculature, the longitudinal fibers remaining unchanged. The newer functional concept regards the condition as a pylorospasm developing on a neurogenic basis. This concept finds support in observations made in the course of operations on these infants. It was noted that the tumor corresponded not to the pyloric but to the antral portion of the stomach. It was, in fact, a prepyloric tumor. The author points to the experience of Lehman, who found that in 10 per cent of the infants with a palpable tumor no tumor was found at the operation. Instead there existed a spasm involving the pyloric and antral portions. This condition termed by Hurst "achalasia," is a functional disturbance in the coordination of the opening mechanism of the pyloric sphincter. For this reason, in Sauerbruch's clinic, these infants are first treated medically in the pediatric clinic. Those who do not respond are turned over to the surgical division. Fifty children were operated on for pylorospasm between 1926 and 1932. Of these, forty-six were boys and four girls. The mortality was 8 per cent. The author attributes these good results to the simplicity and effectiveness of the Weber-Ramstedt operation.

Osteodystrophia Fibrosa Localisata of Long Bones—Bremer and Wienert report seven cases of localized fibrous osteodystrophy observed in the Cologne surgical clinic between 1920 and 1931. The patients were observed for periods of from one and a half to twelve years. The theory of a single gross injury appeared untenable but the possibility of oft repeated insignificant injuries as an etiologic factor appeared likely. The condition first manifested itself almost invariably through a spontaneous fracture. The patients came to be treated at the ages of from 6 to 16 years. The order of frequency of localization was humerus, femur and tibia. The disease pursued the following course in their patients. In only one was there an involvement of the epiphysis with disturbance of longitudinal growth of the bone in one the cyst enlarged as the bone grew. In two spontaneous fracture terminated in healing, in two spontaneous fracture was not followed by deposition of callus.

and in two, healing of the spontaneous fracture was followed by two later fractures. The treatment consists in euretting the cyst cavity. It is impossible to explain why in some cases spontaneous fracture leads to thickening of the bone and healing, while in others thickening does not occur and an operation becomes necessary to obtain healing. The authors likewise report two cases of cyst formation in the distal end of the tibia in which the process, after a number of years, broke through the cortex and involved the soft parts and the skin with a resulting large area of ulceration. One of these patients died of metastases one year after amputation of the leg.

Subcutaneous Adiponecrosis—Sive shows that adiponecrosis is a process strictly limited to the fat tissues and having no influence on the general condition of the organism. He gained the impression that its development is dependent on a high palmitic acid content of the fat, but he admits that trauma (pressure during birth) may be a contributing factor. The importance of the palmitic acid content of the fat is further proved by the fact that when adiponecrosis occurred in adults, the same composition of the fat was found. The author accepts the cellular changes in the tissue as reactions to the altered form and composition of the fat. He shows that the appearance of adiponecrosis in foci contradicts the palmitic acid theory only apparently, because the fat cells are hardly all at the same time in the same stage of development and probably do not have the same composition everywhere.

Treatment of Diabetes in Children—Weichsel tested the efficacy of various dietary treatments recommended for children with diabetes mellitus. He found that a diet with high carbohydrate content, when given for longer periods, may impair the tolerance in cases of medium severity. The protein carbohydrate system proved ineffective even when given only for a short time. A fat and carbohydrate diet of short duration proved favorable. In children, however, this diet (free from animal protein) can be employed only for a short time. Stolte's free diet proved inadvisable in incipient cases, but the author thinks that it can be tried in cases of medium severity. In the so-called total diabetes the free diet proved helpful in some, ineffective in other cases. The author recommends as the method of choice a diet in which the food essentials appear approximately in the ratio in which they appear in human milk. In older children the composition may be changed by increasing the fats and by decreasing the carbohydrates.

New Rapid Pregnancy Reaction—The so-called thirty hour reaction described by Reiprich employs morning urine, because it contains the hormone in the most concentrated form. Following filtration and the addition of a drop of trisecresol the urine is injected under the skin of the back of infantile or

juvenile rats weighing from 40 to 50 Gm. Rats of this weight tolerate from 10 to 14 cc of urine in the course of six or nine hours, while smaller rats may die of lesser doses. As a rule, the urine is injected in two or three doses at intervals of about six (or six and three) hours. The positive reaction, which is evident thirty hours after the first injection, consists in hyperemia and enlargement of the ovaries to two or three times their normal size. The ovaries of the control animal that is given injections of urine from a nonpregnant woman remain pale and small. The reaction does not require microscopy, as it can be detected with the naked eye. However, the histologic studies that were made to determine the nature of the changes disclosed (1) intense blood perfusion of the tissues and dilatation of the vessels, (2) accelerated growth of the otherwise still small or medium sized follicles, and (3) a beginning luteinization. The author says that an accident led him to try the rat as a test animal, because in the course of experiments for other purposes he discovered the great resistance of the rat to comparatively large amounts of urine and decided to utilize this property for the pregnancy test.

Dehydrating Action of Low Carbohydrate Intake—In studies on the dietary treatment of diabetes mellitus, Adlersberg and Porges observed that the ratio between fat and carbohydrates influences also the water exchange of the organism, and they decided to investigate this problem. They found that the carbohydrates have a water retaining action. This storage of water does not take place in the blood but rather in the tissues, particularly the skin. On the other hand, a diet deficient in carbohydrates has a distinct dehydrating action and in this manner has an antiphlogistic effect. The low carbohydrate diet can be employed with good success not only in edemas of various origins but also in inflammatory exudates, for the limitation of the quantity of sputum in bronchiectasis and, finally, as an "antiphlogistic diet" in certain inflammatory processes.

New Gonococcic Antigen—Witebsky's antigen is prepared in the following manner. A strong suspension of various strains of gonococci is left to stand for several days in 50 percent alcohol. Then a certain small amount of lecithin, the exact quantity of which is determined in preliminary tests, is added to the "stock antigen." The antigen is not filtered and thus consists of dissolved and nondissolved parts and should be well shaken before it is used. A measured quantity of the well shaken gonococcic antigen is put into a small porcelain dish and is evaporated in the water bath. Immediately following the evaporation, the residue is mixed with physiologic solution of sodium chloride so as to obtain five times the volume of the evaporated extract, and 0.25 cc. of this suspension serves as antigen. The test is a complement fixation and should use four different amounts of patient's serum inactivated by keeping it for half an hour at a temperature of 56°C. The serum, diluted 1:3, is put into four test tubes to the respective amounts of 0.25, 0.15, 0.1 and 0.05 cc. The difference in volumes is made up to 0.25 cc. by the addition of sodium chloride solution. Then 0.25 cc. of the antigen suspension and 0.25 cc. of 1:15 diluted serum from guinea-pigs are added. The mixtures are then placed for one hour in the incubator at 37°C. Then 0.5 cc. of a mixture of equal parts of sheep's blood suspension and of diluted amboceptor is added. The diluted amboceptor should correspond to from four to five times the dose of completely dissolving amboceptor. Then the test tubes are again incubated. Control of serum and extract is necessary. To control the serum it is sufficient to mix the largest dose of serum with 0.25 cc. of physiologic solution of sodium chloride and 0.25 cc. of guinea-pig serum diluted 1:15. Control of the extract is performed by mixing 0.25 cc. of the diluted extract with 0.25 cc. of the sodium chloride solution and with 0.25 cc. of the 1:15 dilution of guinea-pig serum. The reaction is read following hemolysis of the controls and a second time after renewed incubation of from one-half to one hour. In clearly positive reactions, even the second reading shows complete inhibition of the hemolysis. Only the reactions that prevent hemolysis in at least two dilutions of serum should be considered positive. The author employed this complement fixation test on several thousand serums. He considers the specificity satisfactory, the only difficulty being the differentiation from tuberculous processes. About its sensitivity he states that the reaction is

still negative in new infections because from two to three weeks is required before the antibodies in the serum are sufficiently characterized

Iodine Therapy in Internal Medicine—Liebig calls attention to the fact that free iodine in solution has great affinity for living tissues and that this property is the basis of its antiseptic, hyperemic, anti-inflammatory and resorptive actions. The author shows that iodine is readily absorbed by the organism and explains its action in promoting secretion and dissolving mucus. After emphasizing the value of iodine therapy in tertiary syphilis, particularly in gummas, he discusses the practicability of iodine treatment in atherosclerosis. He describes his own studies and reviews those of other investigators on the mechanism of action of iodine in atherosclerosis. He found that iodine increases the combining power of the serum for cholesterol, and he thinks that this prevents the lipid infiltration of the vascular intima and thus explains the action of iodine at least partially. He discusses the influence of iodine on the metabolism and particularly its effect on the thyroid. He calls attention to the value of iodine salts in the treatment of poisoning by heavy metals, especially in lead poisoning.

Nervous Rheumatism in Girls and Women—Milner discusses a form of nervous rheumatism that is found mainly in girls and women, the incidence being five times as high in women as in men. The men who develop this form of nervous rheumatism are frequently exposed to wet and cold. The disorder becomes manifest in the form of severe pains in the legs and feet, often erroneously ascribed to flatfoot formation and wrongly treated. In the arms, the nervous rheumatism frequently leads to more or less extended pains that radiate primarily from the region of the "small shoulder joint" (acromioclavicular joint) and go through the arm, sometimes to the fingers, but also to the neck and to the upper regions of the thorax and of the scapula. When the rheumatic pains appear in the trunk, they are easily misinterpreted as results of an internal disorder and may lead to unnecessary operations. The author sees the main cause of this nervous rheumatism in the too light and unsuitable clothing worn by women, and he thinks that proper clothing is one of the main factors in the prevention and treatment of this form of rheumatism.

Fatal Mercury Poisoning Originating in Vagina—Montzka reports a case of mercury poisoning originating in the vagina and ending fatally on the tenth day. At the site of action the mercurial preparation produced extensive corrosions with grayish-white coating, superficial necroses and, in the deeper layers, suppurative inflammations. The other toxic effects differed from those that follow the oral intake of the poison only by the absence of changes in the stomach and jejunum. The author reviews other cases of poisoning produced by mercurial suppositories or by vaginal irrigations with solutions of corrosive mercuric chloride, and he describes one case in which a man gave himself a mercurial enema to counteract an ovum. The latter case is noteworthy because it proved the efficacy of dextrose and sodium bicarbonate in mercurial poisoning. The author points out that, in the nephroses of acute poisoning by mercury, roentgen therapy is occasionally helpful. He emphasizes that mercurial poisoning from the vagina is not entirely rare but that its diagnosis may be difficult as the patient may keep the vaginal irrigation secret because it was done for the purpose of inducing abortion. In

doubtful cases the chemical analysis of the excretions may clear up the case, but it should be remembered that the elimination of 0.01 mg is normal, since minute quantities of mercury are contained in the foods.

Serologic Cancer Diagnosis by Lipoid Flocculation—Lehmann-Facius describes several methods or modifications for the improvement of the serologic diagnosis of cancer by lipoid flocculation. Centrifugation of the serum-antigen mixtures was a requirement for all these tests. The author mentions the following as the characteristics of the serologic diagnosis of malignant tumors: 1 Interventions on the antigen in place of the primary alcoholic carcinoma extracts, certain of their fractions were used, namely, the phosphatide fraction that is insoluble in acetone and certain fatty acids. 2 Interventions on the serum first by precipitation of the euglobulin fraction containing the antibody. In this process a further purification and an improvement of the method was obtained by the preparation of the subfraction soluble in sodium chloride. The phosphatide fraction and the cephalin fraction extracted from it proved to be suitable antigens. It was necessary to employ these extract fractions in the form of dense suspensions, which were obtained by slow dilution, in the course of the preparation, a slight lecithinization of the phosphatide extracts proved helpful. Further, intensification of the reaction capacity of the tumor serums was tried by first treating them with hydrochloric acid. Flocculability of the carcinoma serums was actually produced thereby, provided the action of the acid had been sufficiently intense. The acetone soluble fatty acid fractions of the alcoholic carcinoma extracts served as antigens. About half of the carcinoma serums that had been treated with acid produced flocculation also with a suspension of oleic acid. The inclusiveness of the reaction differed with the use of the various extracts and was independent of the histologic type of the original material. 3 The antibody nature of the reacting substances in the tumor serums was proved by separation experiments. It was found that the oleic acid suspension is capable of combining antibodies from the globulin of the tumor serums, which are separated by thermic influences and which, by a flocculation reaction, can be demonstrated again in the separation fluid.

Anaphylactic Shock—Zechinall investigated the theories on the pathogenesis of anaphylactic shock that stress the significance of the potassium content of the serum and that assume a glycogen intoxication. He found that passively sensitized guinea-pigs show during anaphylactic shock a considerable increase of the potassium content of the serum. Potassium salts administered intravenously are eliminated from the blood stream of sensitized animals much more slowly than from that of normal animals. This proves that the sensitization process changes this function. Injection or glycogen into the blood stream does not produce anaphylactic shock in normal or in sensitized animals and the author considers it improbable that glycogen plays a part in the pathogenesis of anaphylactic shock.

Tendency to Edema in Pregnancy and Obesity—Barath and Weiner show that during pregnancy and in obesity a latent tendency to edema may exist in persons in whom edema is not evident. Studies carried out by von Korman and von Farl as disclosed that disturbances in several physical and chemical factors, particularly in the equilibrium of the colloid osmotic pressure and the venous pressure, are the cause of this tendency to edema. The authors studied these factors on pregnant and on obese persons and reached the same conclusion, namely, that the colloid osmotic pressure is decreased and that thus the equilibrium between this pressure and the venous pressure is disturbed. The authors illustrate the differences in the relationship of these two factors in normal persons and in those presenting a tendency to edema by entering the values of these factors into a system of coordinates.

Influence of Potassium-Calcium on Blood Pressure—In comparing the potassium calcium quotients of the blood and of the cerebrospinal fluid in patients having various types of hypertension, Lowenstein detected a relative increase in calcium and a relative decrease of potassium in the cerebrospinal fluid when the values were compared to the conditions found in the blood. Although the absolute numbers remain within the limits of the normal fluctuations, it may be assumed that this change in the ratio of the cations of the blood to those of the cerebrospinal fluid is not an entirely indifferent matter. There is no evidence that these changes are the primary factor in hypertension, for they imply the existence of lesions in the central nervous system. However, in case of an increased irritability of the centers regulating the blood pressure, even a slight deviation in the electrolytic composition of the cerebrospinal fluid, which of course always accompanies a change in the reaction of the fluid (normally more alkaline than the blood), may produce changed impulses in the sensitive sympathetic centers. Thus the authors believe that the electrolytes and their quantitative changes in the cerebrospinal fluid and in the blood exert an influence on the development of hypertension. The first links in this pathogenic process are probably toxic, trophic or other still unknown processes that cause changes in the composition of the cerebrospinal fluid. These changes in turn, by influencing still more susceptible centers, cause hypertension and, parallel with it, deviations in the electrolytic status of the blood.

Calcium and the Action of Strophanthin—Boger and Diehl, summarizing the results of their studies on animals and their observations on human beings, state that calcium produces an influence on the circulation of patients showing cardiac compensation similar to that produced by digitalis preparations. A therapeutic dose of calcium, administered without digitalis, influences particularly the peripheral circulation, in that, similar to digitalis, it exerts an antagonistic action on the sympathetic nervous system. The influence of calcium on the sympathetic becomes manifest in an increase in the peripheral resistance, which, as the authors were able to show, is not due to an increase in the circulatory volume. The influence on the vagus shows itself in a considerable decrease in the frequency of the pulse which, just like that produced by digitalis, leads to a

prolongation of the diastole but leaves the systole practically unchanged. The acceleration of the velocity of the pulse was following administration of calcium, which runs parallel with the increase in the vascular tonus caused by vasoconstriction, likewise indicates the similarity of the action of calcium and of the digitalis preparations. The authors investigated whether the action of strophanthin could be increased by calcium in patients having cardiac decompensation. They found that especially in patients presenting an insufficiency of the left heart a further increase in the circulatory volume can be obtained by giving an injection of calcium after the strophanthin has been administered. This observation is especially valuable for cases in which the stasis is in the lesser circulation (for instance, in acute pulmonary edema), since by further increasing the heart volume it is possible to lead more blood from the lesser to the general circulation.

- *Roentgen Treatment of Certain Metrorrhagias E. Husted — p. 91

Roentgen Treatment of Certain Metrorrhagias—Husted concludes that roentgen treatment is indicated in cases of irregular glandular hypertrophy of the endometrium in older women when diagnosis has been confirmed by histologic examination. In patients in the middle and late thirties, curetting of the uterine mucous membrane should be followed by expectant treatment, if recurrence sets in, roentgen treatment is in order, though possibly not until after repeated curettage. In young women, treatment should consist of possibly repeated curetting in case of frequent recurrence or of exhaustion due to the hemorrhages, roentgen treatment should be given to bring about a temporary menostasis. Extirpation of the uterus should be a last resort reserved for the rare cases in which the hemorrhages cannot be controlled by roentgen treatment.

- *Induced Abortion on Medical Indication Two Hundred Cases P. Külmel — p. 1013
- *Later Fate of Our Eclampsia Patients A. Olsen — p. 1019
- *Endogenic Adiposity—Elityran' V. Brandt — p. 1026

Induced Abortion—Külmel finds that, even when performed on proper medical indications and by practiced technicians under the most favorable external circumstances, induced abortion is accompanied by a grave risk and he states that the statistics available from Russia emphasize his point of view. There were in his material a primary mortality of 1 per cent, graver hemorrhage in 8 per cent of the cases, lesions in more than 10 per cent and infection in 18 per cent.

Later Fate of Eclampsia Patients—From his after examinations, Olsen concludes that neither the course of later pregnancies and births nor the patient's later state of health affords evidence for the interruption of pregnancy solely on the basis of an earlier eclampsia or eclampsism.

- Occurrence of Endemic Goiter in Denmark T. Dalsgaard Nielsen — p. 1067
- Change in Wassermann Reaction J. R. Vgreh — p. 1069

Ochronosis—Bouet's patient was admitted for treatment of a typical carbolochronosis after daily use for three and one fourth years of a 2 per cent solution of phenol on a large ulcer of the leg. Ulceration was present from the condyle of the tibia of the right leg to the lowest point of the tibia, with small ulcerations on the anterior and posterior parts of the knee, which was almost fixed at an angle of from 40 to 45 degrees. The entire leg was noticeably atrophied. The skin of the face and the cartilage of the ears were discolored. Roentgen examination revealed marked halisteresis of tibia and fibula. Amputation of the leg was done. The pronounced anemia, exhaustion and lack of appetite are regarded as undoubtedly due to intoxication with phenol and phenol derivatives. The increased phenol in the urine, even five or six weeks after the end of the treatment with phenol, is thought perhaps to result from elimination of phenol that may have been bound in the organism. This case, together with previously reported cases, warns that careful attention is necessary when a patient is found to have started treatment with phenol.

THE PROSTATIC PROBLEM

A REVIEW BASED ON DEVELOPMENTS OF THE
PAST THREE YEARS

OSWALD SWINNEY LOWSLEY, MD
NEW YORK

There has been a tremendous wave of excitement and enthusiasm about vesical neck resection, which has swept the whole country. It seems to me most appropriate to stop and take stock to see whether such an avalanche of cases is justified.

A great deal of attention has always been paid to obstructions at the vesical orifice. A knowledge of the presence of the prostate gland and its abnormalities was known to the ancients.

The history of early efforts to relieve prostatic obstruction by various instruments has been presented so often of late that a repetition here is unnecessary. Suffice it to say that the instruments were so inadequate and operations on the prostate improved in quality so materially that open surgical operations on the prostate were the procedures of choice. The development of safety factors and the resultant low mortality in this procedure cannot be carelessly laid aside on the appearance of improved mechanical instruments.

In our community there are some ten million souls, which means that there must be about five million males. Our clinic is not the largest in the country but it is and always has been a very active one. We average about 1,000 cases a month in our outpatient department in addition to the private cases of the twenty-four members of our staff. It is therefore evident that we have a great volume of cases to examine from which to choose our operable cases.

Up to May 1, 1933, we have done 144 closed vesical neck operations over a period of twelve and one-half years; therefore we listen with amazement to the reports of tremendous numbers of cases from the clinics of others with little if any more volume of patients than we ourselves have. There are reports of 300, 500, and one ambitious person has even reported over 900 cases of vesical neck resection, all done within the last three or four years. One may draw only one conclusion from these voluminous reports and that is that there are hundreds of patients being operated on who do not need the operation at all.

Some of the most active proponents of vesical neck resection openly promote the resection of any enlargement of the prostate whether there is residual urine or not. I cannot condemn this procedure too much

because every one knows that vesical irritation due to enlargement of the prostate can often be cured by hot rectal douches, prostatic massage and the like. Furthermore, if one slices off the intra-urethral projecting part of the gland, the prostatic ducts are sealed off and the resulting scar prevents the proper drainage of pus, detritus and prostatic fluid, so that the prostate becomes a serious focus of infection. Thus this procedure can be considered only as meddling surgery and should be discountenanced by the thinking members of the profession.

A decided objection to the tidal wave of vesical neck resections is the fact that many physicians who are not properly trained surgeons are doing vesical neck operations. Such persons are not prepared to decide on the proper procedure to pursue or to do a prostatectomy, should it be the operation of choice.

It is my opinion that a urologic surgeon should be prepared to do any type of operation, not only on the urinary organs but on any part of the anatomy bordering on the urinary organs. The following is a case in point.

W. T., a white man, aged 62, admitted to the hospital Nov. 29, 1932, had had the prostate gland removed at a hospital in Panama. On admission, the bladder was draining through a suprapubic sinus. November 30, a vesical neck resection with the Kirwin instrument was done. December 5 after a positive diagnosis of carcinoma had been obtained from the laboratory, ten seeds containing 20 millicuries of radon were introduced into the prostatic bed. His convalescence was uneventful until suddenly, December 8 he had severe pain in the right lower quadrant, and hemorrhage from the bladder was suspected. A suprapubic exploration showed no evidence of a rent in the bladder, and a right rectus incision was made to determine the cause of the trouble.

The peritoneum was opened and immediately revealed a moderate amount of free fluid. The wall of the intestine was injected and a walled off ruptured appendix abscess was found. The appendix itself could not be definitely located. A large Penrose drain was inserted into the bladder and another into the abscess cavity. The patient progressed very well following the second operation. At one time it was necessary to put tubes down into the appendicular incision and irrigate with surgical solution of chlorinated soda. The suprapubic drain was removed and a catheter inserted and, Jan. 7, 1933, the patient was discharged with a retention catheter in place to return to his home in Norfolk, Va.

Having decided to operate on the patient by means of vesical neck resection the surgeon then proceeds to prepare the patient for the event. This preliminary preparation must be accomplished with as much thoroughness as for any type of prostatectomy. I protest vigorously against the common practice of minimizing vesical neck resection, particularly atrocious and untrue is the statement that it is a mere office procedure. My own experience and that of others particularly that of Dr. Alcock convinces any right-thinking person that this is as serious an operation as exists in surgery and

From the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital.
Read before the Section on Urology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 1, 1933.

is not to be taken lightly in any sense of the word. I do not consider it necessary to go into the details of the preliminary preparation of the patient for prostatectomy, as that subject is now well understood by all urologists and most general surgeons. Suffice it to say that drainage should be accomplished by any necessary means until the patient is in as good general condition as he can be, as indicated by renal functional tests, blood chemistry and the like. A preliminary bilateral vasectomy is advisable.

TECHNIC OF THE OPERATION

The anesthesia used should be regional as that is commonly considered to be the most suitable in cases of urinary disturbance.

The instrument to be used is the one with which the operator is most familiar. In our clinic we prefer the Kirwin vesical neck resector with the McCarthy unit, manufactured by Mr. F. C. Wappler. We use the Kirwin instrument because the end is protected, the vision is perfect and the pieces always come out. It is most important for the operator to confine his activities with this tremendously potent cutting device to the lower third of the vesical orifice. Any incision outside this area may lead to disaster, as the wall of the bladder neck at other points is thin and easily cut through.

If the field becomes clouded, one must irrigate until vision is perfect or wait until another dry. Cutting in the dark is too dangerous and should be discountenanced absolutely.

All the bleeding of a serious nature should be controlled on the operating table. If it is impossible to do so with intra-urethral instrumentation, a suprapubic cystotomy should be done and the bleeding stopped under direct vision if necessary. If there is not excessive bleeding, an intra-urethral indwelling catheter size 22 or 24 F. is placed in position and held there by adhesive tape.

POSTOPERATIVE CARE

If the operation has been long continued and considerable blood lost, the patient is given an intravenous or subcutaneous infusion of physiologic solution of sodium chloride or Ringer's solution. The discomfort suffered after the effects of the anesthetic have worn off is controlled by hypodermic injections of codeine, and if these are not effective morphine may be used.

It is wise to keep at least 50 cc. of boric acid solution in the bladder at all times so that any blood occurring there will be well mixed with the solution and no jelly-like clots may collect to interfere with the passage of fluid out through the catheter. The bladder should be emptied every two hours and 50 cc. of fluid replaced for a period of about eight hours. Longer periods may be allowed to elapse between evacuations after this time. All fluids introduced into and returning from the bladder should be measured.

The scrotum should be elevated even when a bilateral vasectomy has been performed.

The hemoglobin should be taken before operation and daily thereafter, if indicated. If it drops to a dangerously low level, whole blood transfusion, as practiced by Dr. Rufus Stetson of New York, should be given, repeatedly, if necessary.

The urine of almost all prostatic patients is infected. The prostatic fluid always contains pus in clumps and a generous flora of bacteria. Therefore a major disturbance such as vesical neck resection is almost universally followed by cloudy infected urine, which persists for a long period of time.

The cut surface develops a slough which does not come away entirely for many weeks, and it is not uncommon for the urine of patients thus treated to be cloudy for several months. This almost never results seriously, although it annoys the meticulous patient. We have noticed that the older and more decrepit the patient, the more extensive the slough and the longer the persistence of cloudy urine.

All patients complain of frequency and dysuria after operation and some of them have difficulty in emptying the bladder for a long time. Many have some residual urine for a few days. A great many patients, however, pass a much better stream of urine from the beginning than was possible before operation, and some of them have very little pain.

It is our practice to irrigate the bladder daily while the patient is in the hospital and frequently for the first month after he leaves. A sound is passed at weekly intervals for two months after the operation and occasionally thereafter. Prostatic massage, hot rectal douches and sitz baths are recommended in many cases and found to be very beneficial.

A summary of the cases treated by vesical neck resection comparing the old Young punch cases with

Comparison of Results of Suprapubic Prostatectomy, Perineal Prostatectomy for Adenoma and Carcinoma, Young Punch and Vesical Neck Resection in the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital up to May 1, 1933

	Total Number of Cases	Average Age Years	Average Post operative Stay, Days	Total Num ber of Deaths	Mortality Rate per Cent
Suprapubic prostatectomy	70	62	25	8	11.43
Perineal prostatectomy for benign hypertrophy	535	68	21	26	4.8
Perineal prostatectomy for carcinoma	79	63	26	16	20.25
Vesical neck resection	89	57.7	13.4	9	10.11
Young punch	53	46	9.5	3	5.66
Total	828			62	7.48

the new vesical neck resections and the results of perineal and suprapubic prostatectomy is expressed best in the accompanying table, which is self explanatory.

COMPLICATIONS

Our experience is limited to a small group of carefully selected cases, and yet, even under almost ideal conditions, we have had every possible complication that we have ever experienced with prostatectomy.

Incontinence after this operation is rare, but we have experienced it in our group of cases several times. We are under the impression that it may occur as a result of too wide distention of the urethra, particularly of the external sphincter, both by the instrument and more particularly by the indwelling catheter afterward. It is our practice at present to use a rather small catheter after the operation. We feel that if it is not left in position too long there is not so much danger of permanent incontinence.

In this series of cases, all types of hemorrhage have been experienced. Profuse bleeding has occurred on the operating table, requiring the greatest amount of ingenuity to control it. In one case the bladder had to be opened and packed four hours after resection, although the condition was apparently under control when the patient left the operating room.

Another patient suddenly began to bleed four days after operation and the hemorrhage was so violent that

the bladder was opened and packed, and his life was saved by giving him an immediate blood transfusion.

A most interesting case of delayed hemorrhage was the following:

J. V., a man, aged 39, readmitted on several occasions recently, left this hospital, Oct. 24, 1932, following a surgical operation on the urinary bladder neck known as a "vesical neck

ing upward as far as the diaphragm had absorbed the blood and, when dissected out and squeezed, gave up the blood just as a sponge would.

Two cases in our series have sloughed through at the vesical orifice resulting in pelvic cellulitis and peritonitis, and, in spite of prompt operation, as soon as the condition was recognized death resulted in both instances.

Our case of appendix abscess following vesical neck resection has already been described. Fortunately, prompt operation and efficient drainage saved the man's life.

Epididymitis is very common following vesical neck resection unless bilateral vasectomy is performed.

Recurrence of the condition is to be expected, as it is absolutely impossible to remove all the prostate with any instrument thus far devised. In our series we have had several recurrences already. All but one of these patients insisted on having the prostate removed by open operation. The one on whom another vesical neck resection was done said he would give the method one more chance and if it was not successful he would have the open operation.

WHAT OPERATION SHALL THE SURGEON PERFORM?

The question naturally arises, When shall the surgeon do a vesical neck resection, when shall he do a suprapubic prostatectomy and when a perineal prostatectomy?

It is my opinion that a vesical neck resection should be done when the patient's symptoms are accompanied by

- 1 An enlargement of the subcervical group of glands with or without residual urine
- 2 A fibrous bar at the vesical orifice
- 3 Moderate adenomatous enlargement of the prostate with not too much tissue intruding into the bladder,

Fig. 1—Moderately enlarged middle lobe with slight enlargement and intra urethral intrusion of lateral lobes. Hypertrophy is not yet too great to permit satisfactory resection.

resection." Two days later, October 26, he returned to the hospital complaining of having seen blood appearing in voided urine, and of passing small blood clots when urinating. At the time of that admission he remained in the hospital until October 29, when he was discharged as having improved.

November 5, he again returned to the hospital complaining of having voided bloody urine. At the time of this admission, it was found that bleeding was fairly well controlled, and the treatment given was conservative, however, November 12, recent hemorrhage was noted by the appearance of bright blood in the urine, and after efforts to control the bleeding had proved unsuccessful and distention of the urinary bladder from blood clots appeared, the indication for suprapubic cystostomy for control of the hemorrhage was evident. Accordingly, cystostomy was done under gas-oxygen anesthesia and the bleeding vessels about the vesical neck were ligated. The vesical neck was packed with petrolatum gauze to aid in control of hemorrhage. The postoperative course was quite uneventful and the patient was discharged, November 29, improved.

A man presented himself at our clinic who had had a prostatectomy performed some years previously. He gave a history of recurring symptoms. Rectal examination revealed no enlargement in the prostatic region. Cystoscopy showed a slightly distorted vesical orifice, but the real trouble was found in the prostatic urethra, where there was a nodule about the size of a small marble. This seemed to be an ideal case for the use of the resectoscope. Accordingly one of my associates easily and efficiently removed the nodule in toto. The patient did well for a few days and then began to show evidence of dehydration, lowered vitality and finally shock, although there was less than the usual amount of bleeding. In spite of every effort on our part he died. Autopsy revealed a most amazing condition. Apparently at the time of the operation the wire had burned bare through the prostatic capsule near its apex but behind the triangular ligament a sizable vessel had bled outside the urinary tract. The areolar tissue extend-

Fig. 2—Moderate hypertrophy of middle lobe but such marked intra urethral enlargement of lateral lobes as to leave no room for the manipulation of the resectoscope. Such cases must be subjected to prostatectomy.

in which there is present residual urine, or when there is a history of repeated attacks of retention or difficult urination.

- 4 All possible cases of carcinoma of the prostate gland.

A suprapubic prostatectomy is the operation of choice when the main mass of the greatly enlarged

gland intrudes into the lumen of the bladder. Perineal prostatectomy should be performed on all others. Examination of the interior of the bladder either by cystoscopy or by observation at the time of suprapubic cystostomy for drainage tells the operator what type of procedure to follow.

Vesical neck resection is wrong in principle in cases that show evidence of absorption from a grossly infected adenomatous prostate. Partial resection of the mass results in sealing off the infected tubules of the prostate so that it becomes a serious focus of infection. The experiences that the members of the medical profession have had with similar treatment of the tonsils is ample reason not to make the same mistake. Such prostates should be removed entirely, and a partial operation is a serious menace to the health and life of the patient.

BENEFITS OF VESICAL NECK RESECTION

There are certain types of cases in which resection of the vesical neck is definitely indicated and when,

Fig. 3—This tremendously enlarged prostate should be removed by open operation as adequate removal with the rectoscope is impossible.

properly performed it will result in spectacular relief of symptoms, which is most gratifying to the patient and the physician.

One of this group is illustrated by the patient suffering from an enlargement of the subcervical group of tubules. These patients have a maximum of symptoms, including frequent, painful urination and nocturia. They may have very little residual urine, which usually is clear. My own anatomic studies have shown that this lesion occurs in almost 25 per cent of all males over 30 years of age.

When a suitable patient is satisfactorily operated on by this method, he may expect to reduce the length of his hospital stay, and after the slough has come away and his urine is clear and sparkling it is most cheering to have brought this about without open operation.

ANALYSIS OF DEATHS

It is instructive to review the cause of death in our failures with a view to the prevention of future calamities.

Our first death occurred in a white man (L. C.), aged 44. He had a moderate intravesical intrusion of the subcervical group of tubules. This was removed with one of the new instruments. He showed evidence of shock some hours later. Suprapubic operation with drainage of the bladder and perivesical spaces, infusions and transfusions failed to prevent his death, Dec. 3, 1931, two days after the original operation.

The second death was that of H. D., a white man, aged 64, suffering from adenomatous hypertrophy of the prostate gland. A vesical neck resection was done, Jan. 26, 1932, under spinal anesthesia. He died from pneumonia fifteen days later.

The third patient to die was J. S., a man, aged 67, who was operated on, Feb. 25, 1932, for the removal of a recurrent tag of prostate that caused obstruction. He reacted poorly and finally went into a deep and fatal shock. His death occurred on the second day following operation. Autopsy showed extensive postperitoneal hemorrhage, which could have possibly have been relieved by a second operation.

The fourth death was that of P. H., a man, aged 57, who had a carcinoma of the prostate with obstruction. He was subjected to vesical neck resection, Sept. 14, 1932, with implantation of radium. He gradually became weaker and weaker, finally dying, Oct. 16, 1932. Autopsy was not obtainable.

The next death was that of R. G., a man, aged 70, who was suffering from a moderate sized, benign adenomatous prostate. He had a vesical neck resection Sept. 21, 1932. The following day he suffered from a cerebral hemorrhage and died.

The sixth death was that of B. H., a man, aged 60, suffering from extensive carcinoma of the prostate with retention of urine. A vesical neck resection was performed, Sept. 30, 1932. He seemed to be doing excellently for a time but had a turn for the worse and died, November 7, the thirty-eighth post-operative day, of uremia.

The next death was that of R. T., a man, aged 76, who had a large adenomatous hypertrophy of the prostate gland. It was prevailed on to do a vesical neck resection by the patient who had read an article in the newspaper on the subject. It was not a suitable case, the prostate being too large to have this procedure done. He did not do well after the operation. He suffered more than the usual pain, there was more than the usual bleeding, and finally suprapubic pain developed. A suprapubic opening the second postoperative day revealed a prevesical infiltration of urine and pus. He died of shock that night.

The eighth fatality was that of J. W., a man, aged 64, operated on by one of the most competent members of my staff, Jan. 16, 1933. He died that night following an exploratory incision to determine the cause of his great shock.

The last death in this series occurred Feb. 18, 1933, three days after vesical neck resection for carcinoma of the prostate. Secondary open operation was necessary in this case also, in order to stop hemorrhage and repair a rent in the bladder.

By a review of these deaths it is noted that any kind of complication common to open prostatectomy can and does occur even in very carefully selected cases. Non-fatal complications of all sorts are possible and do occur in this group of patients.

CONCLUSIONS

Vesical neck resection has a definite place in the armamentarium of the profession for dealing with certain types of enlargements at the vesical orifice. In fact, the new instruments recently developed have materially widened the scope of the Young punch. When successful, this procedure is economical for the patient and gratifying to his physician. The field for its employment, however, is limited. It is unwise to attempt this procedure on massive adenomatous prostates. It is particularly illogical and improper to remove partially a prostate filled with pus which is being absorbed because of the fact that the tubules are sealed off, and it becomes a serious focus of infection. One should take a leaf out of the book of knowledge regarding tonsillectomy and not repeat mistakes in this regard.

On the other hand it is ideal for patients suffering from carcinoma of the prostate, small projections from the floor of the vesical orifice, and fibrous bars

This operation is far from being an office procedure, the avalanche of statistics seems to indicate that many patients are being operated on who do not need it. It is just as important to safeguard a case suitable for vesical neck resection as any other prostatic case. All the usual preoperative tests and maneuvers for improving the patient's general physical condition should be performed.

Patients on whom vesical neck resection have been performed are subject to all the complications that have occurred in our prostate series.

Our mortality rate is 10.11 per cent in a series of eighty-nine cases, which is approximately the same as that of our suprapubic prostatectomies. The lowest mortality rate, 4.8 per cent, occurs in our series of 535 perineal prostatectomies for benign adenomas.

899 Park Avenue

ABSTRACT OF DISCUSSION

DR OMAR F. ELDER, Atlanta, Ga. A careful rectal and cystoscopic examination gives one an idea as to the size of the prostate. Air cystograms should always be made for stones have been found in many of these cases and it is well to know this beforehand. Dr. Lowsley states that there is a place for resection and I firmly believe that in 99 per cent of all types of obstruction resection is the key. It is a question of technique and if one knows what one is going into one can relieve the patient of his obstruction. In the case of a very large prostate, such as is rarely found, one can use the loop and remove a portion and a week later do the regular resection. Dr. Folsom likes to remove the whole thing in one bite, which may be better in some cases.

DR J. R. DILLON, San Francisco. When I began to attend these meetings some fifteen years ago there was generally a yearly battle as to the relative merits of suprapubic and perineal prostatectomy. About the time the old groups decided to pursue their own course in the method each one was particularly trained, a new group of resectoscope operators lined up against the old groups. Allied with this new group of 'resectionists' is found an army of commercialists with an array of instruments and electrical units. These allies are reaching the public by sending advertising literature along with reprints, as well as by salesmen to interview physicians, especially those with a small hospital or connected with an institution that has not installed an outfit. The men in teaching institutions are besought by small town practitioners who want to be taught in from two to ten weeks the simple spectacular operation of taking out a prostate transurethrally. Many of these men do not own and have never used a cystoscope. Urologists have made splendid progress in the last fifteen years in lowering the mortality rate in prostatectomies in both suprapubic and perineal groups. It was learned years ago that any prostatic nodule overlooked in the course of a prostatectomy will enlarge and produce obstruction in from three to six years in an older more debilitated and more damaged cardiorenal patient. Injections en masse and much more careful inspection of the prostatic capsule under vision have practically eliminated these secondary prostatectomies, and one can confidently assure the patient that he will live out the remainder of his life with no serious urinary disturbance. In the few instances in which they do come back with a new growth it is with a carcinoma which has started in the posterior lamella and is never removed in either open or closed methods. There have been localized carcinomas removed in lateral lobes by the open method. These were undoubtedly cancer cures in many instances and must be reckoned with in the ultimate mortality ratios. Most of the statistics on the resectoscope operations are based on all operations including contracted bladder neck types. The resectoscope has come to stay as a development of the punch operation pioneered by Young, Caulk, Collins and McCarthy. I shall continue to limit its use to contracted bladder necks

and to moderately hypertrophied prostates giving obstructive bladder symptoms, with little or no residual urine in men who are still sexually active. In such cases I have had a high percentage of gratifying results. But in old men who have a residual urine, and an impaired cardiorenal system, who have to go through a stage of preoperative treatment and run the same operative risks and complications, I cannot see the sense in avoiding the proved permanent result of an open prostatectomy.

DR N. G. ALCOCK, Iowa City. I would like to invite Dr. Lowsley to the Scientific Exhibit in order to show him the charts and exhibits of every patient operated on. I would like to invite him to Iowa City, to have him go over every case in the hospital. I am sure he would say after seeing them that I would be very foolish to do anything else. The number of cases of prostatic patients that I can handle now is limited to the number of available beds. Previous to resection I was limited to about 100 prostatectomies a year. Now a bed that formerly took care of one patient takes care of four.

DR O. S. LOWSLEY, New York. I believe every word Dr. Alcock has told us. I wish all of us were as open about statistical reports as our chairman. His results have been spectacular and it was his report at Toronto that rejuvenated me in my dying enthusiasm for this procedure, and I now have eighty-nine cases to report.

LOW BACK PAIN

WITH SPECIAL REFERENCE TO THE ARTICULAR
FACETS, WITH PRESENTATION OF AN
OPERATIVE PROCEDURE

RALPH K. GHORMLEY, M.D.
ROCHESTER, MINN.

Many theories have been presented regarding the pathologic changes that underlie low back pain. The subject is still far from settled, although year by year knowledge of the condition improves. To any one who studies the skeleton, the vertebrae particularly, and their anatomy, the importance of the articular facets in the function of the spinal column must be obvious. Further study of a series of spinal columns will reveal that in many of them are changes around the articular facets which must produce symptoms.

The articular facets must be regarded as the only true joints in the spinal column.¹ As true joints, hyaline cartilage covers their surfaces and synovial membrane lines their articular capsules. This articular capsule is more redundant and loose in the cervical region than in the lower portion of the spinal column. It has seemed to me that many of the aches and pains which are known as "backache" are true pains of the joints. They represent the same type of pain as that seen in arthritis of the knee or hip, and the accompanying changes are characteristic of degeneration or traumatic arthritis. The pains are often static in type, that is, they can be relieved by assuming a certain posture, or they can be greatly exaggerated by assuming other postures. The severe exacerbations of pain sometimes experienced are more like the pain of a 'locking' joint than any other type of pain.

The degenerative changes that are characteristically seen in hyaline cartilage may be seen in the articular cartilage of these facets together with the eburnation of the underlying bony trabeculae. This degeneration may go on to complete loss of the cartilaginous surface,

From the Section on Orthopedic Surgery, the Mayo Clinic.

¹ Cunningham, D. J. Textbook of Anatomy. New York: William Wood & Co., 1933, p. 50.

and irregular hypertrophy of the margins, similar to that seen in the advanced stages of degeneration or hypertrophic arthritis of other joints. Thus, the setting is present for a syndrome the same as that seen in many cases of hypertrophic arthritis of the hip, knee or other joints.

It must be realized, too, that there is a more or less constant strain on these articular surfaces, particularly those of the lumbosacral articulations. These surfaces act as stabilizers for the entire spinal column. They are so placed as to prevent forward slipping of the

Fig 1—Right and left oblique views of lumbosacral joint showing a right lumbosacral articular facet with marginal changes suggesting a fracture and b left lumbosacral facet with hypertrophic change of traumatic origin

body of the fifth lumbar vertebra on the sacrum. Any destruction of the integrity of the surfaces under consideration may result in such slipping or in the production of spondylolisthesis. All motions of the spinal column are transmitted to these articular surfaces and even the slightest movement of the lumbar region may result in motion between them. Such movements, if there are arthritic changes in the articular facets, are likely to produce pain. The constant pressure of the surfaces of the facets, one against another, may likewise produce pain, which in many instances is hard to relieve because of the difficulty of getting the surfaces separated by any movement or maneuver whatsoever. The heavy lumbar musculature tends to hold the surfaces firmly against each other, and if spasm is set up in these muscles the surfaces are clamped tighter together.

LITERATURE

Several authors have mentioned the articular facets in the production of the complex of lame back. Goldthwait² pointed out the importance of anomalous placement of the facets and considered their relationship to certain cases of pain low in the back. He did not, however, note any changes except anomalous position of the facets, and their occasional dislocation. He seemed to regard the transverse processes as more likely to cause pressure on the nerve roots. Danforth and Wilson³ have given the most accurate anatomic picture of the lumbosacral joint. They pointed out several important facts. First, the intervertebral foramen between the fourth and fifth lumbar vertebrae is always the smallest, second, the fifth lumbar nerve root is usually the largest, third, the fifth nerve root is directly anterior to the posterior articulation between the fifth lumbar vertebra and the sacrum, and effusion

within this joint might easily cause compression, and, fourth, in the anatomic specimens "hyperextension of the spine caused the posterior superior articular facets of the posterior joints to be driven upward toward the inferior intervertebral notches of the vertebra next above and in this way diminished the size of the intervertebral foramen and might conceivably compress the nerve to some extent." The importance of changes in the facets in production of sciatic pain is obvious. These authors referred to the narrow fifth lumbar disk in some of their cases. Ayers⁴ pointed out narrowing of the fifth lumbar disk as a cause of backaches and noted that in cases of excessive lordosis the greatest strain is thrown on the articular facets.

Key,⁵ in 1924, stated that he regarded strains of sudden onset, low in the back, as true sprains, with tears of the ligaments or articular capsules, and further stated that "the referred pains are perhaps due to irritation of the fourth and fifth lumbar nerve roots by an exudate or synovitis of the adjacent joints."

Putti⁶ presented the whole subject of the importance of the articular facets in the Lady Jones Lecture in 1927. He quoted Goldthwait and Danforth and Wilson, and considered anomalies as well as pathologic changes of the articular facets as causes of sciatic pain. He stated that "the diseased joint, by its swelling and deformity changes the shape and capacity of the foramen, thus irritating and compressing the nerve within it." Again, in 1929, Ayers⁷ reviewed the subject, pointing out the importance of the narrow fifth lumbar disk and of the facets, and the fact that the nerve root

Fig 2—Projected surface of sacro-iliac joint. The level of the lower margin of the sacro-iliac joint runs parallel with the upper margin of the sacrosciatic notch.

passes through the intervertebral foramen between the disk and the facets. Brown⁸ noted the changes seen in the relationship of the articular surfaces of the facets

in various postural changes of the lumbar part of the spinal column. Williams,⁹ in his description of the clinical picture of a "reduced lumbosacral joint space," or narrowed fifth lumbar disk, referred to the articular facets, although it is difficult to tell from his discussion how important he regarded them as causes of sciatic pain or backache.

THE "FACET SYNDROME"

There is ample evidence in the literature that others have regarded the facets as causes of sciatic pain. I

Fig 3—Lumbosacral facet on the right (a), with marked hypertrophic changes. b same region after resection of the facet had relieved the sciatic pain. The patient had spondylolisthesis with sciatic pain and in spite of excellent bony lumbosacral fusion by bone graft the sciatic pain persisted.

feel not only that they are causes of sciatic pain, but that they may be causes of lumbosacral pain with or without sciatic pain. Particularly those patients who complain of sudden onset of pain low in the back, brought on by some activity, often trifling in its severity but usually involving a twisting or rotary strain of the lumbosacral region, are, in all probability, usually victims of the "facet syndrome." These patients often present sciatic scoliosis, which may be homolateral, contralateral or alternating. With the onset of sciatic scoliosis, muscle spasm sets in, and this, although splinting in action, forces the irritated surfaces of the facets together more firmly. Until this muscle spasm subsides or some change in position of the surfaces of the facets takes place, as by manipulation, the pain may persist. Actual sciatic pain may or may not be present at once. It often appears later in the disorder to complete the facet syndrome.

In those cases in which the roentgenogram reveals narrowing of the fifth lumbar intervertebral space, with consequent flattening of the disk, much abnormal strain must be thrown on these facets. It is obvious that, with narrowing of the disk, overriding of the surfaces of the facets must take place. This can be demonstrated by oblique views of the lumbosacral region. With this abnormal contact, traumatic arthritis is likely to be set up, which in time must produce symptoms not only of lumbosacral pain but of sciatic pain as well. In fact, the sciatic pain in these cases seems more likely to be caused by pressure on the nerve or nerve sheath exerted by the facet than by the intervertebral disk. It is possible, too, that the surfaces or margins of the facets may be fractured by undue stress or strain. In some cases seen at the Mayo Clinic (fig 1) it has been possible to obtain roentgenologic evidence of such marginal changes in these articulations as could come

about only through fracture of the margin of the joint, such as can be seen occasionally in any of the smaller joints. The mechanical strain placed on these surfaces when the spinal column is forcibly hyperextended must be great, such traumatic changes probably are present in many more instances than heretofore have been recognized.

ROENTGENOLOGIC EVIDENCE

The satisfactory demonstration of changes in the articular facets has not been possible until recently. Kirklin and I¹⁰ have presented a method of demonstrating these changes which seems to us much more satisfactory than any method heretofore used. Anteroposterior views of the lumbar and lumbosacral portions of the spinal column may show the facets of the upper lumbar vertebrae clearly, but the facets between the fifth lumbar vertebra and the sacrum are usually so placed that they do not show clearly in an anteroposterior view. The same is often true of the facets between the fourth and fifth lumbar vertebrae. Stereoscopic roentgenograms of this region, however good, often leave one dissatisfied as to the changes that may have taken place in the facets. The views already referred to as oblique views, or three quarter views, show the joint space between the articular facets clearly. In instances in which there is anomalous place-

ment of structures little can be told even from oblique views but when the structures are in their usual situation one can accurately determine the presence of irregularities in the joint space as well as changes along the margins of the facets.

TREATMENT

Treatment of this condition may be said to fall into two categories. If the condition has been present a short time only, and if no treatment of any consequence has been given, conservative measures, such as recumbency, with or without traction on the lower extremities, physical therapy, and possibly epidural injection of anesthetic substances are advocated. This entire subject has been covered in a recent article by Craig and

Fig. 5—Combined lumbosacral bone graft and sacroiliac fusion operation showing the lumbosacral bone graft in place. me.¹¹ Our paper dealt particularly with sciatic pain. In many of the cases considered in the present article, sciatic pain is the main symptom, so that cases of the sort considered here made up a fairly large proportion of the cases studied by Craig and me. If conservative measures do not bring relief, it is necessary to choose one of the following: further conservative treatment, more radical measures, such as manipulative procedures or long recumbency in plaster casts, or ultimately radical operation. I feel that a comparatively small group of patients are amenable to surgical treatment. One can pretty safely assure the patient that in time he will be relieved by conservative types of treatment. But in many instances the period of time over which the patient may suffer from recurrent attacks of low back pain, with or without sciatic pain, is so prolonged as to make surgical procedures of real value, provided they leave the patient sufficiently improved to justify them.

It has been my experience that younger persons who have well established recurrent backache of this type are likely to have a very prolonged period of recurrent attacks. Among older persons, the tendency seems to be toward gradual lessening of the severity and frequency of the attacks, probably because of the natural

process of ligamentous and articular change which accompanies age. Hence, it is best, usually, to select only younger patients for surgical treatment.

Failure of conservative treatment alone should not be an indication for operative treatment in these cases. In a general way, it may be said that operation is justified only in the following circumstances:

1 The patient must have persistent pain low in the back, with or without sciatic pain or recurrent attack over a period of months.

2 The pain must be consistently localized over a definite area, with tenderness on pressure over either the lumbosacral joint—that is, the space between the fifth lumbar spinous process and the first sacral spinous process, or laterally in the region of the lumbosacral articular facets—or he must have tenderness over one or both sacro-iliac joints. This tenderness is localized along the upper border of the sacrosciatic notch, which is directly over the sacro-iliac joint (fig. 2). Such tenderness may be found also in the presence of lumbosacral lesions, in which event pain along the superior gluteal nerve is common. This makes the differential diagnosis between these conditions very difficult at times.

3 Narrowing of the disk between the fifth lumbar vertebra and the sacrum must be demonstrated in the lateral roentgenogram.

4 Obliterative or destructive changes in the intervertebral articulations must be demonstrated by the oblique roentgenograms of the lumbosacral region.

5 The central nervous system should have been examined and found negative, except for such evidence of irritation of nerve roots, or of pressure on them, as can be noted in many of these cases.

Fig. 6—Preparation of the bed for the lumbosacral bone graft and the method of removal of the graft. A portion of the articular facet has been excised to break the bony wall of the intervertebral foramen.

With these conditions satisfied, one may consider operative treatment with a fair assurance of success, but the importance of the presence of these factors cannot be emphasized too much. If the pain low in the back is caused by disturbances in either the lumbosacral or sacro-iliac joints, or both, fusion of these joints should relieve the pain. If the sciatic pain is the result of diminution in the size of the foramen of exit of the

11 Craig, W. McK. and Ghormley, R. K. The Significance and Treatment of Sciatic Pain. J. A. M. A. 100: 1143-1149 (April 15) 1933.

fifth lumbar nerve root, enlargement of that foramen should relieve the pain

OPERATION

The type of operation chosen in these cases is, of course, important. Production of lumbosacral ankylosis by bone graft or bony fusion cannot always be depended on to relieve these patients. In some cases even in which there was unquestionably excellent bony fusion or ankylosis, sciatic pain persisted, thus, in spite of the fact that apparently the lumbosacral lesion was the original cause of the backache (fig 3). Removal of the facet resulted in relief of the sciatic pain. Such procedure alone can rarely be risked as a cure for sciatic pain. I¹² have reported a case in which removal of a portion of the articular facet, thus enlarging the foramen of exit of the nerve, resulted in cure of severe sciatic pain. Recently the patient wrote that he had remained well. The day may come when it will be possible to select all the patients whose trouble lies solely in the facet and who can be cured by its partial or complete removal. However, in the light of present knowledge, bony lumbosacral ankylosis must be produced, and, at the same time, sufficient bony and cartilaginous material resected from one facet or from both to remove a portion of the bony wall of the foramen through which the nerve root passes. Perhaps in many cases ankylosis of these joints will produce the desired result. I believe this is true in those cases in which backache only is the predominating symptom, but if sciatic pain is present in addition to the backache, in most instances enlargement of the foramen is essential, and this can be most easily accomplished by excision of the articular facet.

A review of the literature on operative treatment of low back pain discloses that seven distinct operative procedures have been in more or less constant use. They may be grouped as lumbosacral or sacro-iliac operations or as combined fusion operations. The lumbosacral operations most often used are the Hibbs operation, the transsacral fusion operation of Chandler, and the many modifications of Albee's application of bone transplants from the tibia. Smith-Petersen, Crippell, Gaenslen and Verrall have devised operations designed to stabilize the sacro-iliac joint. All these operations have their advocates.

If operative treatment has been selected, the attempt should be made to determine exactly whether the pain is sacro-iliac or lumbosacral. Criteria for selecting patients for operative treatment have been laid down in this paper. If the symptoms cannot be satisfactorily localized to one joint, two or even all three joints may be treated by operation. In examining patients there are many helpful tests and signs, notably, raising of the straight leg, flexion of the thighs on the abdomen, Goldthwait's sign, Gaenslen's sign, and so forth. However, no sign is so consistently informative as elicitation of tenderness on point of pressure. It is of value to be able to demonstrate this tenderness, consistently localized on several examinations at varying intervals. Any case in which tenderness shifts is not a case for operative treatment.

When the joints that are to be fused have been determined the incision indicated in figure 4 is employed except in cases in which both sacro-iliac joints, as well as the lumbosacral joints, are to be subjected to opera-

tion. In these cases a transverse incision is used, curving upward, starting at one sacrosciatic notch and extending across the lumbosacral region to the opposite notch. With the exposure of the lumbosacral area either the surfaces of the facets are excised or fused, and the laminae and spinous processes of the fifth lumbar vertebra and first and second sacral segments are freshened. Then, starting at the posterior superior spine of the ilium, the iliac surface is denuded of periosteum and muscular attachments are denuded, down to the superior margin of the sacrosciatic notch. Fusion of the sacro-iliac joint is then effected after the method of Smith-Petersen¹³ (fig 5). Finally a graft of bone is taken from the posterior aspect of the iliac crest including most of the posterior superior iliac spine, this graft is placed in the bed prepared for it, between the fifth lumbar vertebra and the sacrum (fig 6). Such a graft, I think, brings about ankylosis much more quickly than those taken from the tibia. Experimental work, as yet not published has proved this.

The patient is kept on a firm bed, and a Bradford frame is used. A scultetus binder is the only device for fixation applied over the dressing. After twenty-four hours the patient's position is changed from prone to supine every six hours. After five weeks he is allowed to turn himself, and after six weeks he is allowed to be up, wearing a wide canvas body support or corset. Limited activity for two to three months more is prescribed, roentgenograms are taken at the end of four months from operation.

SUMMARY

Pathologic changes in the articular facets underlie many cases of pain low in the back, particularly those in which are present the symptoms here referred to as the facet syndrome. Proof of these changes is in many instances difficult to secure, but much aid in establishing such a diagnosis will be derived from the use of oblique roentgenograms of the lumbosacral region. Before operative treatment is decided on, the surgeon must be certain of the joints to be stabilized or the result may be poor. Combined lumbosacral and sacro-iliac fusion, such as has been described, has proved much more satisfactory than any other type of operative procedure.

The Physiognomy of Disease.—There is a very genuine study in what may be called the physiognomy of disease. Among the more striking and specific physiognomies we include the mitral facies, with its malar hyperemia and dark crimson lips its varying tints of purple and when failure is advanced and the liver engorged its underlying icterus. The drawn, pale anxious gray-lipped hippocratic facies of peritonitis with 'sharp nose and hollow eyes' is fortunately much rarer than it was thanks to the surgeons. And so is the risus sardonicus of tetanus. The broad thick-lipped impassive face of myxedema with the cheeks tinted a delicate rose purple as Gull described it, a slight underlying waxiness, a smoothness of the skin and the receding hair margin and scanty eyebrows is very characteristic but I have known it when inspection was too superficial mistaken for that of mitral disease nephritis and pernicious anemia. The anxious face of hyperthyroidism with prominent eyes and bulging neck presents no difficulties in the well developed case but I have often had cases referred to me in which the cause of a tachycardia or a breathlessness a nervousness or a loss of weight had passed undetected because slight and early eye signs or the fine tremor of the extended fingers had not been observed.—Ryle F. A. The Training and Use of the Senses in Clinical Work, *Guy's Hosp. Gaz.* 47: 421 (Oct. 28) 1933.

TRAUMATIC BACKACHE

PAUL N JEPSON, MD

PHILADELPHIA

Traumatic backache, although not an ideally scientific term, describes clinically a condition familiar to every orthopedic surgeon. A great many articles have been written about backache, but much of the literature is of a general nature without particular regard to specific points of diagnosis and treatment. Since it has been found that a high percentage of these traumatic backs recover under a definite yet simple although perhaps not an original method of handling, it would seem worth while to make this report.

In traumatic back injuries, wherein the predominant symptom is that of pain, there may be a division into three or possibly four classes:

First, those occurring from traumatism on top of a pre-existing arthritis of the spine and pelvis.

Second, those due to traumatism of the soft parts of the back such as muscle, tendon, ligamentous or periosteal tissue.

Third, cases with a predisposition to injury due to faulty posture.

Fourth, cases caused by occupational strain—such as heavy lifting.

This type of traumatic backache has been estimated by Miltner and Lowendorf,¹ in a summary of 2050 cases of lower back pain, to be present in 30 per cent of this number.

It is assumed that not all traumatic back cases will necessarily fall under one of these specific headings. Many cases may be a combination of one or two or even three of these classifications. It is important, however, that the predominating symptoms be brought out and properly classified so that suitable treatment may be instituted. It is recognized, for example, that traumatism may stimulate arthritis of the spine, and it is also conceded that a patient with a traumatic back having predisposing arthritis symptoms is also retarded in recovery if there is an attendant faulty postural strain.

Out of a hundred cases of traumatic backache, Yeoman² reports seventy-seven men as against twenty-three women. The average age was 44, the youngest patient was 18 and the oldest was 72. In my series of fifty cases of backache caused by traumatism there were twenty-four men and twenty-six women. The average age was 38.1, the youngest was 17 and the oldest was 68 (table 1).

In carefully studying the anatomy of the lower part of the back, it would seem from a purely mechanical standpoint that the method of construction is erroneous, for it would seem that nature has put the keystone of the arch of the lower part of the back upside down and has allowed the entire load to come on this inverted keystone. On the other hand, it is known that the lower part of the back is a shock absorber, and, if taken from this standpoint, it is seen that the pelvis and lower part of the spine are ruggedly built. According to Chamberlain's³ method of computation, the male pelvis is normally capable of only one-half to one-third the mobility of the normal nonpregnant

female pelvis. He points out, however, that, when involved, the male pelvis is much more troublesome and the discomfort is more marked than that of the female subject. It is quite obvious that, owing to occupation and to increased opportunities for traumatism, traumatic backache is more prevalent in the male.

As a general thing, according to Ryerson, the younger patients are more apt to have mechanical instability, while the older patients have an arthritic process, which renders the joints more vulnerable to traumatism.

In a true case of arthritis of the spine, in which there has been no history of injury, there is often a history of pain beginning in the lower part of the back and referred to the buttocks and thighs. As a rule there is a loss of the normal anterior-posterior lumbar curve, and there is usually definite limitation of the normal motion of the spine. Often there is attendant muscle spasm and neuritic signs. The diagnosis may usually be made from these symptoms alone, but it is always more conclusive to have a roentgenogram. This usually shows definite hypertrophic bone changes.

In traumatic backache, the seriousness of the condition may grade all the way from a soft tissue strain up to an actual fracture of the vertebral bodies or contiguous structures. The serious type of fracture is, of course, not to be included in this paper, but slight cases of check-fractures or unrecognized fractures brought out by carefully taken roentgenograms are rather common and are definitely contributory to the disability of the patient.

Sprains of the back in varied states of severity and symptoms are very common. The symptoms may be at once present, or they may come on some time after the accident. Their usual causes are violence, coming from an extraneous source or the overstretching of a

TABLE 1—Fifty Cases of Backache Caused by Traumatism

Number of males	24

muscle or tendon, due to unnatural strain or stress. These traumatic back injuries are most frequent in the lumbar region. Second in frequency is the cervical spine, then the dorsal spine, which is the least flexible and the least liable to injury.

The symptoms involved in a case of traumatic backache are, first of all, pain, with usually a history of a blow, a strain or a fall. If the condition is primarily muscular, the pain is intensified when that group of muscles or single muscle is strained. This may be brought out by the fact that, when the back is moved in one direction or another, the pain is increased, and usually there is attendant muscle spasm. In most cases, standing is very painful, in still other cases, it is impossible for the patient to remain seated, so that in any position that he may assume he is most uncomfortable. Often there is discomfort following coughing or sneezing. Riding in an automobile is many times unbearable.

Read before the Section on Orthopedic Surgery at the Eighty-Fourth Annual Session of the American Medical Association Milwaukee June 15 1933.

This pain may be localized or referred. In some cases, the pain is severe enough to resemble a true case of sciatic neuritis, but the condition may be differentiated by bringing out the fact that the pain is rarely that of the peripheral nerves but rather along the course of the distribution of the nerve roots.

Smith-Petersen⁴ classifies the local site of pain as in table 2.

Inferior sacro iliac ligaments and greater sciatic notch	100
Distribution of subgluteal nerve	23
Sciatic nerve trunk	27
Lumbosacral region	3.2

In most low backaches caused by traumatism, in addition to the pain there is a definite pelvic list or attitudinal posture (fig 1). The pelvis appears more prominent on one side than on the other. As a rule, the list is away from the side affected. In Smith-Petersen's group there was a pelvic list in 72 per cent of the cases, and of this number the list was toward the side of the lesion in 32 per cent and away from the side of the lesion in 40 per cent of the cases. In addition to this symptom there is usually referred pain down the posterior aspect of the thigh on the side opposite the direction toward which the pelvis lists.

With the patient standing in the position assumed in figure 1 there is an apparent shortening of the extremity on the side toward which the pelvis is listing. Almost all directions of back bending are limited, but particularly in a direction away from the side of the pelvic list. Usually the straight leg raising test as described by Goldthwait,⁵ when applied on the concave side of the pelvic list, is decidedly limited and causes pain over one or both of the sacro-iliac joints. This pain may sometimes be localized over an area parallel to the lumbar spine, extending laterally, 2 or 3 inches from the midline of the spine.

There are a number of tests devised by different authorities which definitely help, more or less, to localize the site of the low back pain. These tests are important in the differential diagnosis. Among these is forcible compression of the sacro-iliac joints, which will often elicit pain in the affected joint. This can be done either by direct pressure of the examiner's hands over the crests of the ilium or by placing the examiner's knee over the sacrum and forcibly pulling backward over the region of the anterior superior spines.

Smith-Petersen especially emphasizes the symptoms elicited in bending over while the patient is standing.

⁴ Smith-Petersen, M. N. Clinical Diagnosis of Common Sacro-Iliac Conditions. *Am J Roentgenol* 12: 546 (Dec.) 1924. Routine Examination of Low Back Cases with Particular Reference to Differential Points Between Lumbosacral and Sacro-Iliac Regions. *J Bone & Joint Surg* 6: 819 (Oct.) 1924.

⁵ Goldthwait, J. P., and Good, R. B. A Consideration of the Pelvic Articulations from an Anatomical, Pathological and Clinical Standpoint. *Fraction M. C. S. J.* 1: 52 (Oct.) 1905.

sitting or lying. He emphasizes the importance of these various positions as a means of differentiating between lumbar and sacral conditions. With the patient standing, the back is first flexed, then the pelvis is tilted until the hamstrings become tight. The site of the pain will, as a rule, be easily localized by the patient. In the lumbosacral case, forward bending of the back is possible but the tilting of the pelvis is resisted. In the sitting position, the patient with a sacro-iliac joint trouble can usually bend forward quite easily. The same may be said of flexion with the patient lying on his back.

Gaenslen advocates the following procedure. With the patient lying flat on his back, the thigh and knee of one lower extremity are fully flexed. This extremity is held in this position by the patient. The other lower extremity is held fully extended, and pressure is made on the knee. Pain will be demonstrated in the affected sacro-iliac joint.

The Laqueur sign consists of forcing the leg into flexion, abduction and outward rotation, causing pain in the sacro-iliac joint involved.

In Yergason's⁶ chair test the patient is asked to step up onto a chair, with the unaffected leg and without aid. His attention is taken up with the act and if he is malingering he may complain of pain in that leg, whereas a patient with real sacro-iliac joint trouble cannot step from the affected extremity or sacro-iliac joint without pain.

In cases of traumatic arthritis, unless there has been a preexisting arthritis, the roentgen examination is usually negative. Many times there is thickening of the soft tissues about the sacro-iliac joints, and pressure in this area causes pain. If the condition is unilateral, and thus many times is the case, the test brought out by Carnett⁷ can be satisfactorily applied. He believes that the pinching of a liberal fold of skin and fat between the examiner's thumb and one or two fingers is the best method of examining for tenderness. In a normal individual the maximum pinching pressure causes only slight discomfort and not actual pain. In tender areas a mild pinch may cause severe pain. Patients cannot estimate the force of the applied pinch, and their erratic responses quickly reveal the malingerer to the examiner.

In the great majority of cases of back injury, pain and tenderness involve one or both sides of the lowermost part of the abdomen. This region is supplied by the hypogastric and ilio-inguinal nerves. In addition to supplying the lower part of the abdomen both these nerves send sensory filaments to the buttock. The ilio-inguinal nerves supply an area about 1½ inches in width, superficial to and parallel with Poupart's liga-

Fig 1—Right pelvic list.

ment, and likewise a V-shaped area at the uppermost inner aspect of the thigh. If any one of these areas is tender, all four will be found to be hypersensitive. Spontaneous pain is present only in the abdominal area in the majority of patients but a small percentage of patients may complain of pain in one of the three other areas. Very few patients have pain in all four areas. The malingerer is not familiar with the interdependence of tenderness in these four areas and the finding of tenderness in all four areas even when pain is present in only one, promptly establishes the patient's claim as real and not fictitious.

Fig 2—Method of making fracture bed with hyperextension roll

It must be remembered that, in injuries to the back, the condition may be attended by symptoms that are more widespread, serious and undermining in character than those injuries attendant to any other joint. For example, an injury to the knee may be attended by localized swelling and pain and limitation of motion, but under routine treatment of rest and, later on, heat and massage, the joint symptoms usually subside and the patient is able to get back to his former duties without incidental interruption. In the back, such a convalescence is not the routine program. A similar injury affecting the back may be attended by a great deal of pain and limitation of motion. Such a condition rapidly assumes a chronic state, and these cases commonly appear in lawsuits. One has only to "listen in" at the bar to realize just how little is known of a specific nature about this condition.

In the differential diagnosis of traumatic arthritis of the back, there are certain conditions which must be eliminated first. One of the most important things to eliminate is a fracture, and this can be done definitely by means of a clear-cut roentgenogram. There may have been a preexisting hypertrophic arthritic condition, and this also may be eliminated by means of a roentgenogram. The fact that there has been a preexisting arthritis of the spine does not preclude the diagnosis of traumatic arthritis of the back, because, although there may have been a bony hypertrophy, the traumatism will have caused an acute arthritis on top of a chronic condition, affecting the soft tissues, such as the periosteum and surrounding tendons and muscles, in such a way as to produce a localized inflammation with the symptoms previously described.

The treatment in the case of traumatic arthritis of the back should be specific and definite and follow a regulated course.

The prognosis as to recovery of these backs should be as good as it is in other joints, provided the attend-

ing conditions that may contribute toward the physical observations are eliminated. Foot strain is one of these contributing factors, and support should be prescribed when indicated. It is important to eliminate focal infection as a factor. There is little need of bailing out the boat unless the leak can first be stopped.

So far as direct treatment is concerned, manipulation of these backs has been done by several well known men. Ryerson states that so many patients have reported immediate relief after manipulations that their worth cannot be discounted. The most common method is that described by Baer⁸ and is done under an anesthetic with the patient flat on his back. The leg is extended on the thigh, and the lower extremity, moving as a unit, is forcibly flexed at the hip.

TECHNIC OF TREATMENT

The following method of treatment has met with an appreciable amount of success.

First of all, the patient is placed on a fracture bed, preferably in a hospital. Such a bed may be made by taking three boards 10 inches wide seven-eighths inch thick and 5 feet 10 inches long fastened together side by side by means of two cross cleats. This board arrangement is then placed lengthwise on the springs of the bed, and the mattress is placed on top of the boards (fig 2). This will make a bed with firm and positive support. The foot of the bed should then be raised 6 inches from the floor. Buck's type of extension should be applied to both legs. In the case of an adult female, an 8 pound weight is used on each leg. In the case of an adult male, a 12 pound weight is used. Instructions are given to the effect that if the patient is unusually restless these weights may be raised for half an hour from time to time.

The patient is allowed to turn on his side for a change of position, but for the most part he is urged to remain on his back, in order to get the maximum amount of positive support and immobilization. Under no circumstances except for unusual conditions is the patient allowed bathroom privileges. This position is maintained for a period of two weeks. At the end of this time a plaster-of-paris cast is applied with the patient resting on a modified Goldthwait hyperextension frame (figs 3 and 4). The cast is spical and extends from the armpits down to the knee on the side of the referred pain. By holding the back in hyperextension the maximum amount of immobilization is obtained and the position acquired while the patient has been lying in bed is approximately maintained.

Fig 3—Modified Goldthwait hyperextension

When the patient has become partially accustomed to the cast, he is allowed out of bed for a limited time, these periods of freedom are gradually increased as the patient becomes stronger. The cast is kept on for two weeks and in some very severe cases the time is extended to three weeks. The cast is then removed and the back is strapped with adhesive tape. The back brace or corset made from measurements previously taken is applied over this strapping. The adhesive tape is allowed to remain on for four or five days and is then reapplied. A baking and light massage is given between strappings. At the end of two weeks the adhesive tape is finally removed and mild exercises are begun. These exercises are gradually increased in severity and scope.

The patient should continue to sleep on fracture boards similar to those used in the hospital for at least six to eight months

There are certain cases of backache which will not respond to this or any other form of conservative treatment, and it is not advisable to persist in such treatment indefinitely. An operation designed to fuse the bony site of the localized back pain must be considered.

The Smith-Petersen operation is perhaps the most commonly known. This consists in the removal of a rectangular piece of bone crossing the ilium and sacrum and wedging the sacro-iliac joint. This joint is destroyed by curettage or erosion, and the rectangular piece of bone is wedged back in such a way as to cross the joint with cancellous bone. The countersunk block is further secured, and osteogenesis is promoted by turning down flaps of bone from the edges of the window.

Gaenslen advises the division of the posterior third of the ilium into an outer leaf, which is reflected laterally with the muscles attached, and an inner leaf which remains standing. A triangle is marked out on the remaining leaf within the articulating area of the sacro-iliac joint. The joint is eroded, bone fragments are packed into the triangle, and the outer leaf of bone is replaced and sutured.

Campbell⁹ advocates an extra-articular fusion, in the belief that such an operation is less likely to lead to infection.

The fusion of one sacro-iliac joint often does not entirely relieve the patient of pain, and the fusion of both the sacro-iliac joints as well as the lumbosacral junction has been found necessary in not a few instances. This operation is done through three separate incisions, one over each of the sacro-iliac joints and one over the lumbosacral junction. The technique is that recommended by Smith-Petersen. The graft used over the lumbosacral junction is an osteoperiosteal graft, taken either from the crest of the ilium or from the flat internal surface of the tibia.

After operation these patients are placed on a Bradford frame. No cast is applied. They are kept in bed for two months. At the end of this period they are given a brace and allowed out of bed gradually. The postoperative care relative to physical therapy, exercises and the like is much the same as that outlined for the conservative treatment of traumatic backache. The number of patients requiring operation has been found to be comparatively small, for, if the conservative treatment is carried out conscientiously, many of the cases in which it is anticipated that an operation may be necessary will respond so well as to make an operation superfluous. In my series of traumatic backs only nine patients came to operation.

CONCLUSION

My reason for outlining a definite program of treatment for traumatic backache is that the response of and relief to the patient has been extremely gratifying.

REPORT OF CASES

CASE 1—Miss M. R., aged 54, seen in February, 1931, complained of pain in her back which she had had since January of that year. The pain came on suddenly while the patient was doing ethie dancing. She was in bed for a week. She saw an osteopath who said there was a partial slipping of one

of the vertebral bodies. She had light treatment and the back was manipulated, but at the time of this treatment the pain was much worse.

Physical examination revealed that there was a definite pelvic list to the left with an attendant scoliosis. All back motions were limited. The Lasegue sign was one-half normal and painful. The patient had had a recent tonsillectomy. The pelvis had been reported normal and she had had a recent dental examination.

She was hospitalized on a fracture bed with traction on both hips. This treatment was followed by the application of a cast, and following this she had strapping of her back, wore a belt, and had baking, massage and exercises. Active treatment was kept up for seven months and then she was shown exercises which she did faithfully.

Examination in February, 1933, revealed that she had no back deformity and no pain. She is able to do her regular work and to continue her esthetic dancing. The patient was dismissed as having recovered.

CASE 2—Mrs. P. C., aged 44, seen in January, 1930, complained of pain in the back which she had had for three weeks, referred down her left thigh and leg. The pain came on suddenly as a result of a strain from lifting. She had had local applications of heat and local massage. She had had recent dental attention. There was no tonsillitis, and examination revealed normal tonsil tissue.

Physical examination revealed a positive Lasegue sign on the left. There was a definite pelvic list to the left and all back motions were definitely limited.

The patient was hospitalized on a fracture bed with traction on both legs. Following this treatment a cast was applied. After the removal of the cast a corset back brace and strapping

Fig. 4—Patient on hyperextension frame ready for application of a cast.

were applied. Physical therapy was carried on for a time. The back improved but later on began to get progressively worse. Six months after her first visit her back was fused, the Smith-Petersen technique being used to fuse both sacro-iliac joints and the lumbosacral junction. She had an uneventful convalescence.

Examination made in February, 1933, showed that there was absolutely no pain in the back and there was normal motion. She was able to follow her regular occupation as a housewife.

CASE 3—H. B. R., a man, aged 27, seen in May, 1931, complained of pain in the back referred to the right hip and right lower extremity. The patient had had a tonsillectomy two weeks prior to this examination. Pain came on following an injury due to a strain while working on a building.

Physical examination showed a pelvic list to the right with a resulting scoliosis. There was a positive Lasegue sign on the right.

The patient was placed in the hospital on fracture boards with traction to both legs. Following this a cast was applied and then a corset brace. He was shown exercises and given physical therapy. The back did not improve as rapidly as was anticipated. He consulted another orthopedic surgeon and had the lower extremity manipulated. His back still continued to ache. The pelvic list became worse so that in April 1932 the back was fused the Smith-Petersen technique being used and both sacro-iliac joints being fused as well as the lumbosacral junction. He made an uneventful recovery.

Examination made in April 1933 revealed that his back motions approach normal. He has absolutely no pain, and he has returned to work.

CASE 4—Mrs. K. P., aged 50, seen in April, 1930, complained of pain in her back, running down the back of her right thigh and leg. She had had this pain for five months, and it had

⁹ Campbell, W. C. Operative Measures in the Treatment of Acute and Chronic Lumbosacral and Sacro-iliac Articulations. Surg. Clin. N. A. 5:1 (Sept.) 1911.

come on suddenly as the result of a fall. She had had osteopathic treatment and had been in bed. Her teeth had been extracted and she had no history of tonsillitis.

Physical examination revealed that she had a pelvic list to the right. All back motions were limited. She had a positive Lasègue sign on the right.

The patient was placed in bed on fracture boards with traction to both legs. Later a cast was applied. Following the removal of the cast a corset brace was applied and she was instructed in the use of bracing and massage. Her convalescence was slower than usual, but at the time of the last examination, which was in March, 1931, she was able to do all her housework. There was no back deformity, no pain and no limitation of motion.

CASE 5—M. S., a man aged 28 seen in October 1930 complained of pain in the back running down the posterior surface of the left thigh. This came on as a result of an accident four years prior to this examination. He had had his tonsils out and his teeth had been recently examined.

The patient stood with a definite pelvic list to the right. All back motions were limited. He had a positive Lasègue sign on the left and he stood with pronation of both feet.

He was equipped with supports for his feet. He was hospitalized on fracture boards with traction to both legs. Later a cast was applied. On removal of the cast he was fitted with a back brace. He was given exercises, bracing, and massage. Later he went South for some sun exposure. He continued to sleep on fracture boards at home.

In September, 1932, when examined he had no pain. He had returned to work as an automobile salesman and had no back deformity.

CASE 6—D. G., a man aged 24, seen in May 1929 complained of pain in the back coming on as a result of an automobile injury. He had been hospitalized prior to this examination.

Physical examination revealed a definite pelvic list to the right with limitation of all motion of the back. The straight leg-raising test was limited on the left. His feet were slightly pronated.

The patient was placed in bed on fracture boards with traction to both legs. Later a cast was applied and following the removal of the cast a pelvic back brace was fitted. He was given exercises, bracing and massage and at the time of his last examination in February, 1933 he had absolutely no pain and had returned to his former occupation as a milk carrier. There was no deformity.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. GHORMLEY AND JEPSON

DR. HENRY W. MEYERDING, Rochester, Minn. I should like to say a few words which I hope will be of service to general practitioners. When examining injured backs, the first essential is to disrobe the patient, so that careful inspection and palpation can be carried out. The patient then should be made to try to bend forward, backward, to the right and to the left, with the knees and hips stiff, while the hands of the examiner palpate for muscle spasm, deformity and tender areas. Formerly, anteroposterior roentgenograms of the spine were considered adequate, but for some years my colleagues and I have felt that lateral views are of great importance. Impacted fractures, spondylolisthesis, and injury to the intervertebral disks have been much more readily detected in lateral views. As was shown so expertly in the slides presented by Dr. Ghormley another aid is available in the three quarter roentgenograms which reveal the articular facets and sacro iliac joints so well. In classification Dr. Jepson might well include a group of congenital anomalies which exist in the lumbosacral region, and which are associated with traumatic backache. In my recent studies of spondylolisthesis I was able to illustrate a great number of such deformities, which result in weakness of the lumbosacral joint when stress and strain on this region take place, giving rise to symptoms of medicolegal importance. The unrecognized compression fracture seen to occur so frequently from jars and jolts incurred in modern fast automobile driving must also be considered. Hernia of the nucleus pulposus and

injury to the intervertebral disks are observed with increasing frequency in these cases of traumatic spine. Physicians must always bear in mind as a complication of trauma the possibility of malignancy, metastatic or primary, as a cause of backache, especially among elderly patients. I have seen myomata apparently incurred in industry, diagnosed as traumatic backache, which ultimately proved to be the result of malignancy. One should be extremely careful when expressing an opinion that a person is malingering, for it has been my experience in such cases occasionally to find evidence of fractures, arthritis or metastasis. In persistent cases of sciatica or numbness following injury even though there is evidence of spondylitis or arthritic changes in the spine, it is well to have a neurologic examination so as to rule out a tumor of the spinal cord. Dr. Jepson's treatment by Buck's extension stiff bed, corsets, belts and casts is similar to the method carried out at the Mayo Clinic. The facet syndrome has not been generally recognized, and I believe Dr. Ghormley's paper is timely, for the facets are true joints subject to the same stresses, strains, injuries and diseases to which other joints are subject, and with modern roentgenographic technique the physician has the opportunity to study the changes that take place in them and to appreciate their importance.

DR. ROBERT B. OSGOOD, Boston. Dr. Jepson's division into four distinct types may be useful to the general practitioner but I think it is perhaps dangerous if it becomes routine among surgeons whose experience makes it possible for them to think for themselves. For example, not every case of traumatic backache is always associated with sciatic scoliosis, and not every case of sciatic scoliosis is due to trauma. I take it that all of Dr. Jepson's cases were treated by the method he advocates. I should like to see a chart added to the paper, a copy of which Dr. Jepson was kind enough to let me have before this meeting giving an exact diagnosis and a division into his type or a combination of them and the number of cases completely or partially relieved, and the duration of symptoms before relief. In the six cases reported in his paper no exact diagnosis is given and the end results he has reported suggest rather a long period of cure which in case 1, for instance is reported as lasting a year in case 2, two years in case 3 a year and eleven months in case 4 eleven months, in case 5 a year and eleven months in case 6 three years and nine months. Undoubtedly, in Dr. Jepson's cases relief was complete long before that time but it gives the impression that the treatment is somewhat prolonged. Dr. Ghormley has done a real service in recalling to attention the importance of these changes in the lumbosacral and the sacro iliac facets, as have Dr. Goldthwait and Drs. Wilson and Danforth. Dr. Putti, especially in his Lady Jones lecture, has called attention to this extremely common narrowing of the lumen by changes in the facets. There is perhaps no region in the body where anatomic variations are more common not only in the way of sacro iliac changes, but when the potentialities of irritation exist because of unequal leverage and therefore potential strain and traumatic arthritis, with which Dr. Jepson is most concerned. I am of the opinion that very accurate diagnoses will be missed often if the true sciatic pain and associated pain are considered as referred only from lesions of the sacro iliac joint. Tuberculosis of the sacro iliac joint and displacement of the sacro iliac joint are often free from sciatic pain and it gives proper cause for further consideration of referred pain. Probably lumbosacral lesions are more common than sacro iliac lesions, in spite of medicolegal evidence to the contrary. The accuracy of diagnosis should be very much improved by the new oblique technique and the presence of the lesion clearly shown if the roentgenologist can learn the technique accurately. It is a rather difficult technique for the ordinary roentgenologist to learn. The presence of these occlusions of lumens is demonstrated very easily in the collection of spines to which Dr. Ghormley has referred and in the arthritic exhibit here the spines of the hypertrophic arthritis cases show an almost complete occlusion of the facet. We must as a rule then learn the exact anatomic structure and the lesions of the lumbosacral facets if we are to make an accurate diagnosis and apply the proper treatment.

DR. LEWIS CLARK WAGNER, New York. The defective articular facet is most of all to be associated with defects in the pedicle and laminae of the vertebrae. I see many cases of this

sort at the Neurological Institute in New York and the Hospital for Ruptured and Crippled. This type of case sooner or later presents neurologic symptoms and signs. In an analysis of a number of cases of congenital defects of the lumbosacral joint, all of which have been studied and proved, the occurrence of pain was as follows: pain in the sacro iliac region, 10 cases, pain in the vicinity of the lumbar muscle of the affected side, 12 cases, bilateral, 1 case, pain over the sacrolumbar joint, 10 cases, pain on the opposite side, 1, pain in the gluteal muscle and hip, 4, pain over the sciatic notch, none, pain on the outer side of the thigh and knee, 5, pain along the sciatic nerve, 3, numbness about the outer side of the leg and calf, 4, pain about the instep, 5. This next is very important: could produce pain by certain movement, 5, lying down relieved pain, 6, trauma the cause because of sudden fall, 7 cases. As to the duration of symptoms: 1 case, eighteen years, 2 cases ten years, 1 case five years, 5 cases, four years, 1 case, three years, 2 cases two years. Next is the age at which symptoms appeared: 1 case 18 years, 1 at 24 years, 1 at 25 years, 2 at 30 years, 1 at 32 years, 1 at 33 years, 1 at 34 years, 2 at 35 years, 1 at 36, and 1 at 37 years. A man, aged 36, of stocky build, came under my care in 1925 with the history of eighteen years of recurrent attacks of pain, deformity and disability in his spine and left leg. These attacks were brought on by the slightest unguarded muscular activity, such as leaning over to tie his shoe or to lift small objects. He had so much numbness, coldness and atrophy of the left leg that I felt sure he was suffering from a nervous condition. I did not appreciate the anomaly or absence of articular facets in this case until 1930, at which time a lumbosacral fusion was done with complete relief of pain. However, the numbness was the last symptom to disappear. In lumbosacral anomalies the subjective pain is segmental in distribution, being completely localized to the areas supplied by the first, second and third segments. In the cases under consideration, the inflammation about the spinal column and its articulations causes spasm of the lumbar muscles with a physicochemical irritation of them and a great deal of the pull on their periosteal attachments with a further demonstrable tenderness. The rotation of the fifth lumbar vertebra associated with a too adherent dura to the spinal nerves as they make their exit from the vertebral foramina or the narrowing of the intervertebral foramina, must transmit such irritability to the spinal cord over the nerves supplying the muscles, ligaments and periosteum affected.

DR PAUL N. JEPSON, Philadelphia. I think that the suggestion to include the anomalies of the back in my classification, is an excellent one but for the sake of brevity I limited my paper to traumatic lesions only. Perhaps I was unfortunate in the selection of the cases illustrating traumatic backache but these six cases appeared to be rather typical. The duration of the period of disability prior to the treatment varied from four weeks to six months. In those cases requiring operation the disability lasted for more than a year. I want to express my appreciation of the splendid discussion.

DR RALPH K. GHORMLEY, Rochester, Minn. I am glad that Dr. Meyerding and Dr. Wagner mentioned the importance of a neurologic examination. There certainly is nothing more important when one is considering surgery in these cases than a neurologic examination. My own feeling is as Dr. Wagner has mentioned that a lumbar puncture should be done. The technique of the three quarters view or the oblique view will be published shortly. It has been worked out by the roentgenologic department. It is not always easy to get good roentgenograms of this type and much care must be exercised in taking these pictures. Dr. Paine has ably discussed these pathologic changes and advocated extensive excision of these facets. It is a little unwise to remove many facets because the stability of the spine may be so affected that damage may be done. I didn't mention the postoperative care in this type of operation. We put the patients to bed after the operation on a Bradford frame using a scultetus binder. At the end of six weeks the patients are allowed to be up with a canvas belt or corset. Four months later we take check up roentgenograms to make sure that union has taken place. We give them exercises to rehabilitate the muscle which are so severely atrophied at this time.

CARBON DIOXIDE AND OXYGEN IN OBSTETRICS

W. T. McCONNELL, M.D.
AND
ROLAND L. McCORMACK, M.D.
LOUISVILLE, KY.

The presentation of this paper is in the nature of a preliminary report of our observations over the last two years in our private work, and during the past year in the Louisville City Hospital. The subject matter here-with deals principally with the clinical results together with a brief discussion of physiology, in our use of carbon dioxide and oxygen mixtures as a therapeutic agent in the treatment of some complications of obstetrics. We plan, at a later date, to report the results of experimental laboratory studies on this subject. Among the complications thus treated are asphyxia and atelectasis neonatorum, postlabor and postanesthesia shock, uterine inertia during labor, postpartum hemorrhage, the terminal depression of severe toxemia, and postcesarean abdominal distention.

Current literature teems with the controversy between a group of investigators who contend that carbon dioxide is superfluous and harmful to the asphyxiated newborn infant¹ and another group² who claim that oxygen alone is not entirely adequate for resuscitation of asphyxia neonatorum. It is our conclusion after clinical investigation and diligent perusal of the literature that both groups are right as far as they go but that the common ground between them, the use of adequate and intelligently varied mixtures of carbon dioxide and oxygen, will give the desired result in resuscitation when nerve cells of the center have not been deprived of the minimum supply of oxygen and carbon dioxide for the maintenance of fetal existability.

Three years of oxygen administration (1928-1931) with some means of artificial respiration failed to decrease the mortality rate in the asphyxias or to overcome atelectasis, the forerunner of pneumonia. Carbon dioxide alone was obviously not used, but the use of variable mixtures of carbon dioxide and oxygen from 5 to 30 per cent of carbon dioxide, with a full complement of oxygen, for the past two years in our practice of obstetrics and treatment of the new-born enables us to say that we have not failed to resuscitate a single asphyxia patient except one with cerebral hemorrhage and one with a congenital abnormality of the heart. Both infants were premature. We have had no atelectasis that was not easily controlled with the mixtures and have had no subsequent bronchitis or pneumonia. Similar treatment of the new-born in the obstetric service at the Louisville City Hospital, for the past year has yielded equally good results in respect to neonatal pulmonary complications.

An understanding of the physiology of respiration and the pathology of asphyxia is a prerequisite to the intelligent administration of the gases and the results are in direct proportion to the degree of such understanding. The ready-made mixtures of 5, 7 or 10 per

cent of carbon dioxide with their complement of oxygen are safest for the average physician, but they cannot be applied with success in all cases, for we have found that, as a rule, the greater the degree of asphyxia and lowered excitability of the centers, the higher the percentage of carbon dioxide necessary for stimulation. The classic differentiation of asphyxia livida and pallida are examples the pallida being simply a greater degree of asphyxiation and requiring higher percentages of carbon dioxide for stimulation. The laryngeal reflex used as a means of distinguishing the degree of asphyxia has never been used by us, as we feel that it is a waste of time. It is easy to insert a tracheal catheter if response to the mixtures of 20 or 25 per cent carbon dioxide is not shown within a few seconds. When mixtures above 5 per cent are used they must gradually be lowered as response increases so that the respiratory efforts of the child will be stimulated only slightly above normal action. The mixtures should never be given strong enough to cause a gasping struggling, straining type of respiration. The objective symptoms are the guide and the nearer the normal respiratory rate the treatment can be carried out the longer it can be kept up and the more oxygen can be furnished to the tissues.

It has always been our idea to use carbon dioxide as a vehicle for oxygen supply to the tissues. Coryllos³ has shown that oxygen passes more quickly from the air sacs to the blood when a small percentage of carbon dioxide is present.

Our routine neonatal treatment of premature infants includes the administration of 5 per cent of carbon dioxide and 95 per cent of oxygen into a tent for a few minutes three times a day. The length of time of each treatment is determined by the respiratory response of the patient, but the average is about fifteen minutes.

The development of shock during anesthesia and following the emptying of the uterus is mainly due either to the anesthetic or to fatigue or to both. The cause in both instances is ultimately the same for to the acidosis and paralyzing effect of the anesthetic is added the increased lactic acid production of the maternal tissues with displacement of carbon dioxide from the base.

If the degree of acidosis is sufficient to produce a mild degree of shock with splanchnic endorsement, an insufficient amount of oxygen and carbon dioxide is supplied to the uterine muscle to oxidize its excessive load of lactic acid.⁴ A local acid base imbalance remains and increases in the smooth muscle cells with subsequent shock and loss of tone of the uterine muscle, and postpartum hemorrhage then occurs.

All of the mechanical methods⁵ of control of postpartum hemorrhage cause an ischemia of the uterine muscle, thereby defeating any possibility of immediate restoration of function. Therefore the treatment of postpartum hemorrhage resolves itself into the treatment of shock. The administration of carbon dioxide and oxygen, by decreasing the primary acidosis⁶ elevates the general nervous tone⁷ and accelerates circula-

tion,⁸ thereby reestablishing normal tone and function of the uterine muscle.

In shock due to anesthesia, the administration of carbon dioxide and oxygen stimulates the respiratory center, causing an increase in respiratory depth and rate, thereby furnishing more oxygen to the hemoglobin, relieving acidosis, stimulating the heart muscle accelerating circulation and elevating tissue tone.

Something more than one year ago our attention was called in a rather unique manner, to a possible effect of carbon dioxide inhalations as a stimulant to uterine contractions during labor. A private patient who had been having a prolonged first stage with weak, irregular contractions was developing uterine inertia. We thought it likely that she was having a fatigue acidosis and decided to administer several inhalations of carbon dioxide and oxygen to see what clinical effect we would get in combating the fatigue. After a few inhalations we noticed that the uterus began a good contraction, followed by adequate relaxation. After this contraction, we gave the patient a few more inhalations and were gratified to see the contractions occurring with good regularity and force. Our impression was that the carbon dioxide had stimulated normal uterine contractions with normal relaxation periods. Recognizing the possibility of these phenomena being coincidental we employed the same procedure in every case of inertia and found a uniformity of response that removed any reasonable doubt as to its effect as a stimulant. Further observations carried on in the City Hospital substantiated our results.

Among the inertia patients at the City Hospital were a number who had received caudal anesthesia, and in these the response was much slower. Our best results were obtained in inertia caused by fatigue or that developing in connection with the administration of such drugs as morphine, sodium amylal, nembutal and chloroform.

As soon as it seemed fairly well established that carbon dioxide actually did have a stimulating effect on uteri suffering from inertia during labor, we decided to employ it in those cases of excessive bleeding due to inertia following the expulsion of the placenta. Ordinarily there will be only normal bleeding if contractions during the third stage have been strong enough to expel the placenta spontaneously. But there is a certain percentage of cases in which some degree of shock occurs after a physiologic third stage, owing to relaxation of the patient following prolonged, tiring labor, or associated with some form of anesthesia. The degree of shock in most of these cases is so slight that the relaxation of the uterus is the only clinical evidence of depression, or it may rarely become sufficiently severe to have the clinical picture of surgical shock. We feel that, from our observations, this mild form of shock is the cause of more postpartum hemorrhage than has hitherto been thought.

In our private work we have adopted the plan of administering a few inhalations of carbon dioxide and oxygen immediately following the expulsion of the placenta and have had no undue bleeding from the placental site in any of these cases in two years. In the City Hospital we have for the past several months, employed carbon dioxide and oxygen inhalations as a routine in all cases of profuse bleeding from the placental site following the expulsion of the placenta. Records on twenty-five such cases show uniformly

good results. We are reporting briefly four of these cases taken at random from this list as typical of the results we have obtained. In these cases carbon dioxide was not used as a prophylactic, as in our private work, therefore we were better able to study its effect as a therapeutic agent to check a hemorrhage already established.

REPORT OF CASES

CASE 1—R M, a white girl aged 17 years, a primipara and primigravida had a funnel pelvis. The first stage of labor, Nov 7, 1932, lasted thirty-six hours, the second stage, five hours and forty minutes. She was delivered of a female infant, weighing 7 pounds and 4 ounces (3,300 Gm), with difficulty by low forceps under chloroform anesthesia. The blood loss was 600 cc. The patient became cyanotic, and carbon dioxide, 5 per cent and oxygen 95 per cent, was given by inhalation. After ten minutes cyanosis disappeared and the patient's condition became satisfactory. Fifteen minutes later she showed evidence of shock, as bleeding became profuse. The carbon dioxide and oxygen was given for five minutes, while symptoms of shock disappeared, the uterus began to contract and hemorrhage ceased. After this, no evidence of shock or hemorrhage appeared.

CASE 2—M G, a Negress, aged 23, a secundipara and secundigravida, was admitted Dec 25, 1932, with fever of 102 F. The os was completely dilated. She had been in labor eight and one-half hours. Caudal anesthesia was given and she delivered a female infant weighing 7 pounds and 2 ounces (3,230 Gm). The placenta separated spontaneously after twenty-five minutes. The uterus failed to contract, despite the administration of solution of pituitary and ergot, and bled profusely. The cervix was examined and showed no tears. The fundus would not remain hard despite repeated doses of solution of pituitary. The patient went into shock and was given inhalations of carbon dioxide 5 per cent, and oxygen, 95 per cent. She rallied well, the uterus contracted and hemorrhage stopped. Her condition remained good.

CASE 3—B B, a woman aged 39, a quintodecipara and quintodecigravida, Nov 1, 1932, was in a toxic condition, with a blood pressure of 150 systolic, 95 diastolic. At 5 p m she noticed a slight pain and the membranes ruptured at which time 12 inches of cord prolapsed. The patient was put on the delivery table in the Trendelenburg position, and under gas anesthesia unsuccessful attempts were made to restore the cord. The cervix was found to be dilated from 2 to 3 cm. Dilatation occurred rapidly and a still-born male infant weighing 7 pounds and 12½ ounces (3,530 Gm) was delivered by podalic version and breech extraction. Acute pulmonary edema developed during anesthesia and the patient bled profusely from the relaxed uterus, losing 800 cc of blood. The hemorrhage ceased under inhalations of carbon dioxide 5 per cent and oxygen 95 per cent. The blood pressure had dropped to 94 systolic, 58 diastolic. Carbon dioxide was given every fifteen minutes for four hours, at which time pulmonary edema had disappeared. The blood pressure and general condition remained satisfactory.

CASE 4—M B, a white girl aged 16, a primipara and primigravida, June 9, 1933, had been in the first stage of labor forty hours and in the second stage fifteen minutes. She was delivered by midforceps. The pelvis was of the rachitic type. The placenta was delivered fifteen minutes later by the Crede method because of uterine bleeding with uterine inertia before the placenta was expelled. Solution of pituitary, 0.5 cc and one ampule of ergot were given immediately after the placenta was expelled. Profuse hemorrhage then occurred. Solution of pituitary was repeated in five minutes. This treatment combined with massage and pressure failed to stimulate uterine contractions. Carbon dioxide 5 per cent, and oxygen, 95 per cent was given for five minutes. Twenty minutes after the placenta was expelled. Within one minute the uterus developed a firm contraction the first since the placenta was delivered and contractions continued controlling the hemorrhage. About ten minutes after carbon dioxide was discontinued uterine relaxation with bleeding was again noticed. Carbon dioxide was again administered and the uterus again contracted and hemorrhage without further hemorrhage. The blood loss was 1,000 cc.

It will be noted that in cases 1 and 2 some shock was a demonstrable complication of the bleeding, and in case 3 a toxic condition with acute pulmonary edema accompanied the hemorrhage.

In a certain percentage of cases of eclampsia the toxemia becomes so severe that a paralyzing effect on the cardiovascular system takes place, with the result that the elevated blood pressure drops rapidly to far below normal limits, the pulse becomes very rapid and thready and pulmonary edema quickly develops. The patient becomes cold and sweaty, the respirations become slow and shallow, and she dies of the depressive influence of the toxin. We have employed carbon dioxide in five cases of this type with prompt recovery in three. In the two cases in which death resulted, autopsy showed a severe coexistent infection, in one case a well established pneumonia and, in the other, liver abscesses. Both patients had developed postpartum eclampsia in the home and were brought into the City Hospital after a long delay. Case 5 illustrates the success of carbon dioxide therapy in a severe depressive condition such as described, even when the case is complicated with a probable pneumonia, treatment being instituted early.

CASE 5—Mrs P W, a white woman, was delivered by her family physician of a living child at 8 20 a m, Aug 30, 1932. The prenatal history was normal. Soon after delivery a headache developed which increased in severity. Two hours and forty minutes after delivery she began having convulsions and became unconscious. She was admitted to the Deaconess Hospital and seen by one of us (W T M) at 2 p m. The blood pressure was 148 systolic, the diastolic pressure not registering. The temperature was 103.6 axillary, the pulse was irregular and 136 per minute, respirations were 28. Severe pulmonary edema and cyanosis were present. A catheterized specimen of urine showed albumin 3 plus. The diagnosis was postpartum eclampsia. She was given 7½ grains (0.5 Gm) of sodium amytal 100 cc of 50 per cent dextrose and 1 cc of digifoline, intravenously, followed by gastric lavage, 4 ounces of magnesium sulphate saturated solution being left in the stomach. At 3 30 p m her condition was worse and oxygen was administered by tent, with no improvement even in cyanosis. At 6 15, carbon dioxide 10 per cent, and oxygen, 90 per cent was administered for twenty five minutes by tent. The respiratory volume increased. The rate increased from thirty-six to forty-four per minute. The cyanosis disappeared. At 8 30 the blood pressure was 95 systolic, 35 diastolic, the pulse, 128, full and regular. The temperature was 102.2 F. The respiratory rate was 32. The patient answered questions and drank water. Examination of the chest showed only a few scattered fine rales. At 9 15, carbon dioxide, 5 per cent, and oxygen 95 per cent, was again given, being administered fifteen minutes each hour. The patient talked intelligently. At 11 30 a m she felt better. August 31, at 7 30 a m, eleven hours after carbon dioxide and oxygen was started the temperature was 99 F, respiration rate, 28, pulse 100, blood pressure 122 systolic and 80 diastolic. The chest was clear. There was a trace of albumin and the urinary output increased. Carbon dioxide 5 per cent and oxygen 95 per cent was administered three times a day for two more days. The patient made an uneventful recovery.

We report briefly one case of acute yellow atrophy of the liver, occurring post partum.

CASE 6—Mrs L W, a white woman, aged 30, a primipara and primigravida seen in consultation by one of us (W T M) was delivered after forty-eight hours of first stage labor, of a 3½ pound (1,587 Gm) seven month fetus. Owing to a marked congenital cervical atresia, a vaginal cesarean section was necessary to extract the fetus. On the second day following a classic case of acute yellow atrophy developed with almost immediate coma. A continuous flow of 10 per cent dextrose with calcium gluconate was given through a cannula anchored in the vein by venoclisis (Hendon's). At varying intervals the patient's respi-

rations would become very shallow and soon would cease altogether, the pulse becoming very rapid and weak. Artificial respiration forcing carbon dioxide into the lungs was used. After several such forced inhalations breathing would again become spontaneous and within a few minutes would be fairly normal, the heart tone and the patient's color improving. For the first two or three forced inspirations, a concentration of 50 per cent carbon dioxide was used. As soon as respiration became spontaneous, the oxygen percentage was increased to 95 and continued thus for two or three minutes. These attacks became less frequent until after three days of continuous dextrose and intermittent carbon dioxide administration the coma disappeared, the jaundice began to clear up and the patient made a satisfactory recovery.

Abdominal distention following cesarean section is due to shock, paralysis of the splanchnic nervous system, loss of smooth muscle tone and decrease in local circulation. Pressure in the intestine aggravates the condition. An increase in carbon dioxide tension has long been known to stimulate smooth muscle activity. Therefore one would expect the administration of carbon dioxide and oxygen to stimulate peristalsis and restore normal cellular function. We have found in our work in the City Hospital that this hypothesis is borne out by clinical results. Our records show that the gas mixture was used in sixteen consecutive cases with success.

Case 7 is reported herewith as a typical result.

CASE 7.—A Negro female aged 16 years, a primipara and primigravida with a generally contracted pelvis, after a six hours trial labor was delivered of a 6 pound and 11 ounce (2933 Gm.) baby by Phaneuf low cesarean section. About eight hours after operation the patient became distended with gas. After thirty-six hours with no relief carbon dioxide, 5 per cent and oxygen, 95 per cent, was administered for five minutes. This was repeated every half hour for four doses. Immediately after the first administration the patient asked for a bed pan and passed a large amount of flatus and a watery stool. From this time on intestinal peristalsis continued. Before the carbon dioxide administration enemas, colon tube and gastric lavage had been done without any stimulation of peristalsis.

CONCLUSIONS

- 1 From 1928 to 1931 oxygen therapy was applied to all the conditions described, without any appreciable change in morbidity or mortality.
- 2 Carbon dioxide and oxygen mixtures, when administered by the metric control system, have been adequate for the relief of asphyxia neonatorum atelectasis neonatorum and its sequelae over a period of two years.
- 3 Carbon dioxide and oxygen mixtures safely and promptly combated uterine inertia in the first stage of labor.
- 4 The classic mechanical treatment of postpartum hemorrhage does not stand up under physiologic investigation. Hemorrhage is evidently due to postpartum acidosis of the uterine muscle. Carbon dioxide and oxygen controlled twenty-five consecutive cases.
- 5 The abdominal distention following cesarean section was promptly relieved in sixteen consecutive cases, even after thirty-six hours' duration in one instance.
- 6 The practical points in symptomatic administration are that treatment will usually be started with mixtures of between 20 and 30 per cent of carbon dioxide with oxygen. This high percentage is only for stimulation of the respiratory center and must be promptly reduced after a few inspirations, to the percentage that will maintain a normal or slightly higher respiratory rate.

Strict regard must be paid to the fact that even 5 per cent of carbon dioxide and 95 per cent of oxygen will overstimulate in some cases and should then be used for only a few minutes at a time.

321 West Broadway

ABSTRACT OF DISCUSSION

DR. WALTER M. BOOTHBY, Rochester, Minn. The question of oxygen therapy is not limited to obstetrics. However, in obstetrics there is undoubtedly an ample opportunity for its extensive use. For example, as it is impossible to choose the time of delivery, the patient at delivery may have a shock, cold, such as would lead to the postponement of an ordinary surgical operation or, worse, she may have severe bronchitis, or even pneumonia. Under these conditions the proper use of an oxygen tent before and during the early stages of labor would be most helpful. In addition to the beneficial effects of oxygen one can obtain by the use of the modern type of tent the added comfort in warm weather, of an atmosphere cooled 10 or 15 degrees below the room temperature. The disadvantage of oxygen therapy is its expense, but with modern tents and proper arrangement the cost is not prohibitive. Oxygen cannot be properly administered unless frequent analyses are made of the oxygen and carbon dioxide content of the tent air. Oxygen therapy is also of great benefit to either premature or term infants who have any respiratory difficulty. For this purpose a Hess incubator can be easily modified so that it will become a miniature oxygen chamber. The question of the administration of carbon dioxide in addition to oxygen is of course an important one. However, I think the title of the paper, Carbon Dioxide and Oxygen in Obstetrics, emphasizes the wrong point. Oxygen therapy is undoubtedly beneficial, the presence in the inspired air of between 1 and 2 per cent of carbon dioxide will do no harm and may possibly do some good by increasing the depth of respiration. The inhalation of mixtures containing 30 per cent of carbon dioxide as occasionally recommended by some is dangerous and of course cannot be done for more than very few breaths.

DR. E. D. PRASE, Iowa City. I should like to ask the authors what evidence they have that the administration of oxygen and carbon dioxide relieves acidosis and that the stimulation of the uterus in first stage inertia is attributable to a change in acid-base balance. It has been my experience in another connection that the production of acidosis by starvation acts as a very efficient uterine stimulant, inducing labor in from 30 to 50 per cent of patients.

DR. HENRY F. BECKMAN, Indianapolis. May I ask a question? If the carbon dioxide mixture stimulates and establishes respiration after birth, what does it do to the infant before birth when given to the mother?

DR. W. T. McCONNELL, Louisville, Ky. I thank Dr. Boothby for emphasizing certain precautions in regard to the use of carbon dioxide. One of them is that even a weak mixture (5 per cent) can be breathed too long and result in a modified convulsion. Therefore, one must stop it when the physiologic effect has been obtained. The reason we say 5, 10 or 20 per cent when we use the stock mixtures is that that is what is on the carton and is not always what the patient gets when mixed with the air in a tent. When we make our own mixtures with the machine we use we know what they are getting when given by direct inhalation. The extent of depression of the centers governs the concentration needed to revive the patient whether it is asphyxia shock, inertia or hemorrhage. It takes an experienced man to understand the responses in such a way as to administer it intelligently. With regard to the muscle tone of the uterus, all I can say personally is that whatever causes the shock producing the relaxation of the uterus can be relieved by carbon dioxide. Dr. Boothby says it is not carbon dioxide that accomplishes results, but the oxygen. We agree with him. The carbon dioxide is the vehicle by which the oxygen is made available to the tissues. In answering the question with regard to acidosis, I wish to state that there is a marked increase in lactic acid at the end of the second stage. Our experience convinces us that this causes the shock, but whatever it is our clinical results show that weak mixtures of carbon dioxide and oxygen stimulate muscle

tone and accomplish the results. As to what effect it has on the baby before it is born, our observation is that the babies are born in a better condition, need less resuscitation and are of a better color when the mother has been given a little carbon dioxide and oxygen just before the baby is completely born or just after the head is out. We have watched this in a large number of cases and it works out that way. The apparatus we use in our private work is the McCormack resuscitator carbon dioxide machine and it can be seen in the Scientific Exhibit.

PHARMACOLOGIC ACTION OF BARBITURATES

THEIR USE IN NEUROPSYCHIATRIC CONDITIONS

CARL PHILLIP WAGNER, M.D.

Senior Assistant Physician, Neuro Psychiatric Institute and
Hospital of the Hartford Retreat
HARTFORD, CONN.

The barbituric acid derivatives have recently assumed a rather prominent role in the treatment of psychotic patients. Although among psychiatrists interest has primarily centered around the psychologic reaction produced by these drugs, I believe that a concise consideration of the pharmacologic action would not be amiss.

Though in general their action is quite similar, they differ principally in rate of effectiveness, rate of elimination and, to some extent, degree of toxicity. The more commonly used barbiturates can be divided into two groups: the shorter acting drugs, consisting of pentobarbital sodium, amytal and secondary butyl beta bromallylbarbituric acid sodium salt, and the longer acting group, consisting of phenobarbital, neonal, ipral, a barbituric derivative with amidopyrine, dial and barbital. In general, all are somewhat more rapid in their action if combined with sodium. The degree of toxicity has been worked out by Barlow,¹ who gave the order of toxicity, from high to low: secondary butyl beta bromallylbarbituric acid sodium salt, barbital, phenobarbital, amytal, neonal, a barbituric derivative with amidopyrine, dial and pentobarbital sodium.

PHARMACOLOGIC ACTION

Effect on Metabolism—The basal metabolic rate is little affected by barbituric acid narcosis. There is rather a slight initial fall, which then remains constant.² Guinea-pigs which were under the influence of barbiturates and were given thyroid extract showed a rise in basal metabolic rate similar to the controls which had not received the drug.^{2a} A slight fall in body temperature usually occurs.

Some controversy exists in regard to their influence on sugar metabolism. Page³ and Deuel^{2b} found no change in the blood sugar. Isenberger⁴ found no appreciable change in the blood sugar, but stated that in some cases a decrease in sugar tolerance could be demonstrated. Underhill⁵ reported an increase in blood sugar in rabbits. Hines⁶ reported that amytal lessened the ability of the animal to handle dextrose, and he found an increase in blood sugar with glycosuria. In a

later communication,⁷ he reported the muscle glycogen to be about the same in animals with and without amy-tal anesthesia. When dextrose was given intravenously, he found the liver glycogen to be more than twice as high in animals anesthetized with sodium amytal as in unanesthetized animals. Most investigators agree that the increase in blood sugar rarely exceeds normal limits.⁸

Effect on Circulation—A fall in blood pressure has been a constant finding. The most striking fall is brought about by sodium amytal and, when given intravenously, is somewhat proportionate to the rate of injection. The fall in systolic blood pressure is proportionately greater than that in diastolic pressure.⁹ A slight rise in diastolic pressure has been reported.¹⁰ In cases of hypertension, a fall in systolic pressure from 200 to 100 mm of mercury has been noted.¹¹ The fall in blood pressure is less pronounced when longer acting drugs are given. It usually returns to its former level in from thirty minutes to two hours.

The pulse rate is usually slightly increased. On some occasions a decrease in pulse rate has been noted,¹² but this usually occurs when the pulse is accelerated because of excitement.⁹

Vasodilatation of the peripheral circulation is produced, resulting in flushing¹² and, in some cases, in cyanosis.¹³ There is also a resultant decrease in the tonus of the heart muscle.¹⁴ The permeability of the endothelium of the capillaries is altered,¹⁵ and water is directed toward the tissues of the body.

Gruber and Roberts have made detailed studies of the effect of both longer and shorter acting drugs on the cerebral circulation¹⁶ and the coronary circulation.¹⁷ In each case they found that vasodilatation took place when the drug was injected in dilute solution. They concluded that the barbituric acid derivatives acted directly on the wall of the vessel, causing vasodilatation.

Blood Chemistry—A definite fall in the calcium content of the blood occurs.¹⁸ A similar fall in blood calcium has also been demonstrated during sleep induced by other hypnotic agents.^{18a} The changes in potassium content have not been constant; there may be either an increase^{18a} or a decrease.^{18b} The phosphorus and magnesium content is decreased,^{18b} while a slight increase in blood bicarbonate has been found.¹⁹ Depression of respiration causes an increase in carbon dioxide tension.²⁰ The carbon dioxide-combining power is not affected²¹ if respiration is not depressed, as has been shown by the intratracheal administration of oxygen.¹⁹ The hydrogen ion concentration is slightly increased if

the drug is given intravenously,²² the p_{H} value falling from 0.1 to 0.2 unit.¹⁹ Dilution of the blood has been shown to occur and has been explained as being due to an accumulation of corpuscles in the spleen, which is increased in size.

Effect on Respiration—All members of the barbituric acid series depress the respiratory system when doses large enough to produce deep narcosis are administered.²³ The rate of respiration may be decreased,²⁴ but more commonly it is increased.²⁵ The respiratory excursion usually becomes shallow.²⁶ The shorter acting barbiturates produce death by respiratory paralysis,²⁷ in which case the thorax is usually expanded, and pressure on it will permit it to fill. The patient may again resume breathing, since the margin of safety between respiratory failure and cardiac failure is fairly wide.⁹ In prolonged narcosis, especially if the longer acting drugs are employed, pulmonary edema usually occurs, the patient is unable to raise mucus,²⁸ and death may occur from pulmonary congestion or other complications such as pneumonia.²⁷

Effect on Renal Function—When the drug is given in hypnotic doses, the urinary output is usually appreciably diminished,²⁸ but the flow of urine returns to normal within from six to twenty-four hours.²⁹ There is no impairment of glomerular activity, as shown by the phenolsulphonphthalein excretion,³⁰ even when the drug is given in fairly large doses over a comparatively long time.³¹ The urea output is diminished for a period of from four to six hours,¹⁹ while the excretion of urate and phosphoric acid¹⁹ is slightly increased for twenty-four hours following administration of the drug. Acetone has been found in small amounts for twenty-four or forty-eight hours.^{13b}

Effect on Hepatic Function—Some controversy exists in regard to the effect on the liver. Some investigators have found a slight but transient damage to the liver with no delayed injury, and have considered the effect negligible.¹⁹ Others have been able to demonstrate very little action on hepatic function, as shown by the bromsulphalein test,⁹ while, as stated previously, Himes⁷ found the glycogen in the liver to be more than twice as high in animals anesthetized with sodium amytal as in unanesthetized animals when dextrose was given intravenously.

Effect on the Gastro-Intestinal Tract—Few experimental data are available concerning the effect of the barbiturates on the gastro-intestinal tract. A number of clinical observations have been made, and it has been observed in surgical work that nausea and vomiting are considerably decreased when barbiturates are used as premedication for ether anesthesia.^{23a} It has also been noted that they control vomiting in gastric crises of tabes.²⁸ They have been shown to decrease the tonus and amplitude of contraction of the small intestine of rabbits.¹⁴

Neurologic Changes—When light narcosis is induced, a slight and transient nystagmus³¹ occurs with some vertigo, a feeling of inebriation and staggering gait.¹⁴ The patient may also complain of double vision.¹ Under light narcosis the pupils are dilated³² but as the depth of narcosis increases they contract slightly and may become fixed.³³ The corneal reflexes are diminished^{33a} or abolished completely.³⁴ In light narcosis the speech becomes thick and slurred,^{33a} the gag reflex remains intact except in extremely deep narcosis, when it is abolished, and there is a tendency for the tongue to fall back.^{13a}

When the shorter acting barbiturates are given in small doses, the deep reflexes are increased.^{33a} Both the deep and the superficial reflexes are diminished under larger doses, or they may be entirely abolished.³⁵ The skin and sphincter reflexes disappear under deep narcosis.⁷ With the longer acting barbiturates, the reflexes may be augmented in all stages of narcosis.¹⁴ There may be slight relaxation of the rectal sphincter,^{13b} and the tone of the bladder may be lost,⁹ making catheterization necessary. Motor restlessness may be present during narcosis, induced by either the longer acting or the shorter acting barbiturates.^{13a} Both will control convulsions.³⁶ However, if the longer acting drugs are given in large doses they may themselves produce clonic and tonic convulsions.¹⁴ The shorter acting drugs have not been observed to produce convulsions, even in extremely large doses.

The threshold for painful stimuli is decidedly increased,¹² and during deep narcosis no response to painful stimuli can be obtained.^{13a} Pain has been controlled in patients with tabetic crises.³⁸ Seven and one-half grains (0.5 Gm.) of sodium amytal, given intravenously, has controlled pain in a patient suffering from bilateral thrombosis of the iliac arteries when large doses of morphine had failed.²⁸

The Psychologic Effect—The use of barbiturates as premedication in surgical treatment has given valuable information regarding the psychologic effect on normal persons. If barbiturates are given to patients before they are taken to the operating room, the fear and apprehension that are usually encountered are decidedly decreased.³⁷

Additional information has been given by Lindemann,¹² who studied a group of students and observed the psychologic effect induced by the administration of small doses of sodium amytal. His observations uniformly showed a striking change in the emotional attitude of his subjects. All of the subjects stated that they experienced a feeling of well-being and serenity, a feeling of warmth and friendship toward the world in general, and gratitude and appreciation for the kindness and goodness of the persons in their environment. They felt a desire to communicate and a willingness to speak about personal problems usually not spoken of to strangers. The future looked bright, and they anticipated future pleasant activities and experiences without effort or drive to carry out their plans immediately. There was no distortion of objects other than a slight

Brown²¹ Lundy¹³

blurring of vision and occasionally double vision. No hallucinations, dreamlike experiences or apprehensive thoughts were experienced. There was no trace of fear, but only the feeling of relief. The shifting of the emotional state along the depressive elation scale was definitely in the direction of elation. Time was usually underestimated. There was no amnesia for conversation or events during the time the subjects were under the influence of the drug.

In psychotic patients, Lindemann²² and others²⁸ have noted a similar change in the emotional reaction. Restive, seclusive and suspicious patients will communicate more freely and become emotionally warm and friendly under the influence of the drug. They express a feeling of well-being and a desire to retain this feeling.

Mute patients can frequently be made to communicate delusional ideas which could not otherwise be obtained, but the drug has no influence on the structure of the delusional ideas and hallucinations present before administration.

The Toxic Effect—Toxic symptoms may result from an idiosyncrasy to barbiturates. Most commonly they occur from the long-continued use of moderate doses. This is especially true for the longer acting drugs, which tend to have a cumulative effect. Occasionally toxic symptoms occur because of overdosage, either through accident or due to self-administration with suicidal intent.

The toxic symptoms may be divided into three groups: mental symptoms, reactions of the skin and general symptoms. In acute poisoning with large doses, coma usually occurs. The long-continued use of the drugs produces mental changes such as confusion, uncertainty, defects of attention and memory and impairment of ethical and moral senses.³⁰ Delusions of persecution with fearful hallucinations and illusions frequently occur.

Two types of reactions of the skin have been described: urticarial wheals with itching, probably due to an idiosyncrasy, and a toxic reaction characterized by a morbilliform or scarlatiniform maculopapular erythema. The onset of this rash may vary from one day to several months after beginning the administration of the drug. It is accompanied by intense itching and lasts from two to ten days after the drug has been discontinued. It usually disappears with fine bristlike desquamation, and occasionally leaves pigmentation in the skin.

The more common general symptoms include an early subnormal temperature with a slight fever after several days. There may be nausea, epigastric pain and diarrhea. Anorexia is almost always present. Speech is usually thick and the patient may omit words or syllables. Early in acute poisoning the deep reflexes may be diminished or absent. Later they become hyperactive. The pupils are fixed. Diplopia and nystagmus may be present. Ataxia may be present. In extreme cases of long-continued overdosage or acute poisoning with large doses, coma usually results and may terminate fatally.

The shorter acting drugs produce death suddenly by respiratory paralysis, while the longer acting drugs produce death more insidiously with pulmonary congestion, usually complicated by pneumonia.³¹

Pathologic Changes—These changes are quite general for most of the parenchymatous tissue of the body.⁴⁰ The changes although not entirely uniform, do agree in general. The slight variation noted by the different observers has been explained by the variation in the size of the dose taken to produce death and the difference in the time interval between the taking of the drug and the time of death.

There is usually considerable congestion of the capillaries of the brain and meninges with some perivascular hemorrhage and edema. The endothelial cells also show evidence of degeneration. Histologic changes are usually present in the cortex, especially in the deeper layer. The Nissl bodies tend to disappear, and the cortical cells show evidence of degeneration as shown by the disappearance of cell membranes and the presence of granular degeneration products. The cells of all of the important nuclei of the brain stem as well as the cerebellum show similar changes. It seems probable that the cellular damage to the central nervous system is due to the direct action of the drug rather than being secondary to the disturbance of circulation.

Perivascular hemorrhages are usually present in the heart muscle.

The lungs are always congested and may show inflammatory changes.

The effect on the kidney is quite marked. No part of the convoluted tubule is spared, though the distal portion is more affected than the proximal portion. The changes in the glomeruli are less marked, although all show evidence of fatty degeneration.

The liver shows evidence of fatty degeneration. The central portions of the lobes are usually more affected than the periphery.

Capillary congestion with hemorrhage is found in the soft palate, the submucosa of the stomach and the small intestine and mesenteric lymph nodes.

Dosage and Points of Caution—The dosage of the various barbiturates cannot be definitely standardized. Unfortunately all persons do not respond identically to a given dose.⁴¹ A good rule is to start with the dosage recommended by the manufacturer and then to vary it to get the desired effect.

Rules of caution may be observed with advantage. Obese or debilitated patients tolerate the drug poorly, so smaller dosages should be employed. Patients with arteriosclerosis, hypertension^{42a} or myocardial disease⁷ or those with an extremely low blood pressure may react poorly to the shorter acting drugs because of their marked effect on the blood pressure.⁴¹ I believe that the shorter acting drugs should never be given to patients with extreme hypertension. I have observed arteriosclerotic and hypertensive patients complain of extreme vertigo and ataxia after taking even small doses of the shorter acting drugs by mouth.

In patients with respiratory obstruction or pulmonary congestion,⁴¹ these drugs should be avoided because of the depressive effect on the respiratory center, as well as the tendency to cause pulmonary congestion.

Antidotes for Barbituric Acid Poisoning—If acute poisoning with barbiturates is due to taking the drugs in large quantities by mouth, gastric lavage should be employed immediately. If enough of the drug has been absorbed to produce a systemic effect, treatment should be directed primarily toward stimulation of the circu-

latory and respiratory systems. In this connection, epinephrine, ephedrine and caffeine have been employed effectively. They may be used alone or in two or more combinations.^{13a}

Picrotoxin has been shown to antagonize the action of barbiturates quite effectively.⁴² It tends to hasten the return of the body temperature to normal and stimulates respiration. It may be used in combination with small doses of ephedrine which helps to restore the normal blood pressure. Picrotoxin may be given in 0.5 per cent solution in distilled water or in physiologic solution of sodium chloride. Its properties are not affected by heating, and it is quite stable. In rabbits it has been given in doses of from 2 to 5 mg at intervals of from five to twenty minutes until recovery has taken place. Man is somewhat more susceptible than laboratory animals, but it has been given safely in doses of from 5 to 10 mg (Murrell, reported by Maloney^{43a}). It may be given intramuscularly or intravenously. In poisoning by the shorter acting drugs, it should be administered in fairly large doses and given frequently. With the longer acting drugs it should be given more slowly.²⁷

USES IN NEUROPSYCHIATRIC CONDITIONS

The barbiturates can be used with advantage in many neuropsychiatric conditions if the physician always bears in mind the various dangers that may be encountered. The use of the longer acting drugs for the control of epileptic seizures is quite common. The shorter acting drugs have been employed with advantage to control extreme convulsive states when the patient's life is in danger. Sodium amytal has effectively controlled status epilepticus resulting from a tumor of the brain, convulsions of eclampsia, tetanus^{36a} and convulsions due to strychnine poisoning.^{36b} The drug can be given intravenously, and the convulsions are controlled immediately.

In extreme cases the shorter acting drugs may be used to control pain. For this purpose they are, however, less practical than some other means, since the analgesic action occurs only when extremely large doses are given, which result in deep narcosis.^{13a}

The longer acting drugs may be used effectively in the treatment of a psychosis with cerebral arteriosclerosis. When they are given in small doses three or four times a day with potassium iodide, they serve the dual purpose of decreasing agitation and motor restlessness and also aid in the reduction of arterial hypertension. The shorter acting drugs should be used with extreme caution in these conditions, because the fall in blood pressure which usually accompanies their administration results in a feeling of dizziness and may lead to collapse. It should also be borne in mind that the longer acting drugs are eliminated slowly, and the cumulative effect, if administered over a long time, may lead to a delirious reaction.

The problem of securing restful sleep is one that constantly confronts the psychiatrist. There are a number of factors in connection with disturbances in sleep which should be carefully considered. Frequently one finds that a patient is unable to fall asleep on retiring, and his concern and fretfulness about this continue to keep him awake. When sleep finally comes he sleeps soundly the remainder of the night. In such cases a small dose of one of the shorter acting drugs is usually effective, as sleep is induced quickly and the patient

continues to sleep even after the drug has been eliminated, and awakens feeling refreshed.

If the patient's sleep is broken by frequent periods of wakefulness during the night, one of the longer acting drugs should be employed. These drugs act more slowly and should be given from one-half to one hour before the patient retires. If the patient retires immediately after taking the drug, he may become fretful because sleep does not come at once and work himself into an emotional state which makes sleep impossible. Since these drugs are eliminated rather slowly, they frequently cause the patient to feel somewhat "dopey" the following morning. This troublesome symptom can be partially eliminated by reducing the dosage to the absolute minimum that will produce the desired effect.

A third type of disturbance in sleep is frequently met in depressed patients, and more especially in those in the later decades of life. These patients frequently awaken in the early morning hours and find it impossible to fall asleep again. Several hours of depressive preoccupation spent in this way will undo the good effect gained from an active therapeutic program of the previous day, and the patient arises more depressed than ever. The shorter acting barbiturates afford an excellent sedative for these patients. If a small dose of sodium amytal or pentobarbital sodium is given when the stomach is empty, with half a glassful of tepid water, sleep is induced almost immediately. The drug is eliminated in a few hours and the patient awakens to start the day free from the tortures of his depression.

The barbiturates are useful in controlling extreme excitement. In this type of patient, the longer acting drugs are also less effective than the shorter acting drugs. Since they are absorbed rather slowly, the excitement may not be controlled for several hours and then only if large doses are given. In excited patients, in whom extreme exhaustion may prove fatal, shorter acting drugs may be given intravenously or intramuscularly, and deep narcosis closely resembling normal sleep can be induced in a few minutes.

Recently, deep narcosis of several days' duration has been advocated as a means of therapy in the psychoses,⁴³ and various members of the barbituric acid series have been employed for this purpose. The method has also been used in connection with induced fever during the narcosis⁴⁴ or psychotherapy at the time the patient is emerging from the narcosis. In most instances some gratifying results have been obtained. The marked improvement noted has been variously explained on a psychologic, physiologic and biochemical basis. Undoubtedly the rest both physical and psychologic is an important factor. In addition to this, the psychologic phenomena⁴⁵ at the time the patient is emerging from the narcosis, when he is rendered more suggestible, gains a feeling of well-being and shows more confidence toward people in his environment, is an equally important factor.

The results reported from the use of prolonged narcosis seem to justify the use of this procedure in selected cases in which the psychosis does not respond to other means of therapy. When one studies in detail the pathologic findings resulting from barbituric acid poisoning, it becomes apparent that there is some permanent damage to most of the parenchymatous tissue

45 Bleckwenn^{36a}

of the body. Fortunately nature has been generous enough to supply most of the organs with sufficient tissue so that the clinical results in most cases are negligible. If the procedure is carried on for a long period or is repeated a number of times in the same patient, it is conceivable that function may be permanently impaired.

The phase of increased cooperation usually encountered when a patient is emerging from deep narcosis can also be produced by the administration of small doses of the shorter acting drugs without producing narcosis.¹² The intravenous administration of from 3 to 5 grams (0.2 to 0.3 Gm.) of sodium amytal usually produces a striking change in the attitude and reaction of the patient. A similar change, though less striking, may also be brought about by giving from 3 to 6 grams (0.2 to 0.4 Gm.) by mouth before meals when the stomach is empty.

I have treated thirty-seven patients by the administration of small doses of sodium amytal. Almost without exception I was able to obtain better cooperation from negativistic patients for a period of from several minutes to several hours after the administration of the drug. The administration of the drug was continued in doses large enough to maintain this stage of cooperation for a variable length of time, ranging from several days to three or four weeks in the majority of cases.

During the time the patient was under the influence of the drug, psychotherapy in the form of reassurance and suggestion was employed. In seventeen of these cases, improvement was shown from the time that the drug was first administered. Fourteen of the patients continued to improve but five left the hospital before they had recovered, nine made complete recoveries. In three the psychosis again became stationary, but at a higher level than before the treatment was started. In twenty cases the patients again regressed to their former level following the initial period of cooperation, and the treatment was discontinued.

Irrespective of diagnosis, I found that by studying the ideational content of these patients while under the influence of sodium amytal, they could be divided into three general groups. In group one the outstanding feature of the ideational content was extreme autistic thinking. In these patients the psychosis centered largely around themselves with no concern about their environment. Some of these were depressed and complained that they had committed terrible sins. They expressed no ideas of punishment, nor did they think that their sins would cause any trouble or discomfort to others. They showed no concern about their environment. Others thought that people in their environment would also suffer for their sins, but they were not particularly concerned about this. They were chiefly concerned because they had committed some moral wrong. In others of this group, the ideational trend was directed primarily toward the body with ideas of disease or bodily changes but again with little concern regarding their environment. There were nine patients in this group; two (22.2 per cent) showed slight improvement but seven (77.7 per cent) showed no change other than the transient period of cooperation while under the influence of the drug.

The second group consisted of six patients whose preoccupations were directed primarily toward their environment but whose ideational trend indicated that they were not in the least threatened by their environment in their present state. Several of these patients

were somewhat amused by things that happened about them but their affective reaction was somewhat shallow. Others talked about plans for the future in a way that could not be considered expansive, but at the same time expressed an undue confidence in themselves. Nothing in their environment seemed to threaten them in the least. Of these six, none recovered. Only one (16.7 per cent) showed slight improvement, and five (83.3 per cent) showed no improvement.

In the last group consisting of twenty-two patients, the outstanding characteristics seemed to be the decided threat which their environment held for them. Some of these patients were depressed, but, as contrasted with the first group they were more concerned about the punishment which they might receive from their associates while the moral issue of their preoccupations seemed to be secondary. Others showed no evidence of depression but felt quite inadequate and insecure in their environment, while still others showed rather definite paranoid trends. This group responded quite well to treatment, fourteen showed improvement as soon as the treatment was started, nine (40.9 per cent) made complete recoveries and five (22.6 per cent) left the hospital before recovery was complete. Eight (36.3 per cent) showed no improvement.

This short series of cases seems to indicate that the increased feeling of security and the increase in cooperation produced by small doses of sodium amytal may interrupt the course of a psychosis and hasten recovery. The treatment seems to be particularly suited to those patients who feel that their environment is threatening their welfare.

CONCLUSIONS

- 1 Though usually employed for their sedative action, the barbiturates influence almost every system of the body, and their various side actions should be considered in relation to the general condition of the patient.

- 2 The longer acting drugs are eliminated slowly, and the cumulative effect of long-continued usage may lead to a delirious reaction or to other toxic symptoms.

- 3 The psychologic reactions, which are readily induced by the shorter acting drugs, usually help in gaining cooperation from the patient and may aid in interrupting the course of a psychosis and hasten recovery.

- 4 If the drug is given over a long period, the histologic changes produced by the administration of large doses may lead to permanent impairment of function.

ABSTRACT OF DISCUSSION

DR W. J. BLECKWEN, Madison Wis. Being in a great measure responsible for the intravenous use of barbiturates in neuropsychiatry I feel justified in reporting work covering a period of five years, during which more than 10,000 intravenous injections have been made. Practically all of the short and long acting barbiturates have been studied and sodium amytal has been the most desirable of the barbituric acid derivatives now available. The following early conclusions have stood the test of time: 1 A prompt and prolonged hypnosis and narcosis can be obtained in all psychotic individuals. 2 A controlled hypnosis for psychologic study can easily be developed in any psychiatric case. 3 A restoration of a normal sleep cycle in acute excitement enhances the rapid recovery in these cases. 4 The exhaustion states associated with acute toxic conditions which are often fatal can be avoided by periodically induced narcosis. 5 Convulsions associated with tetanus, eclampsia, strychnine poisoning and status epilepticus can be completely controlled. 6 The method as to dilution and rate of injection and criterion of dosage in each individual case described in my first communication, is not

paramount importance. All the disturbing untoward reactions with the great fall in blood pressure are thereby avoided. 7 Intravenous barbiturate therapy is hazardous in cases presenting advanced arteriosclerosis, myocarditis and severe hypertension. 8 In spite of favorable reports, I am opposed to narcosis prolonged for several days. The abnormal metabolism and body chemistry over a prolonged period will not enhance a restoration of normal cellular function. I believe that the production of a narcosis which more simulates the normal sleep cycle is of greater value. Several publications from members of our group are being made establishing the following additional facts: 1 A method of chemical psychoanalysis. 2 A method of investigation in criminal cases. 3 The intravenous use of coramin, caffeine, and epinephrine as an antidote in barbiturate necrosis and the control of the depth of hypnosis induced by sodium amytal by the same drugs. I wish to warn against the general use of barbiturates as practiced. A perfectly good series of drugs can be abused by being employed in every conceivable condition. They are toxic, they are not analgesic, and they have a limited usefulness. They should be used only in conditions in which they are known to be beneficial. My only criticism of this excellent presentation is the author's criterion of dosage, in that he advocates starting with the dosage recommended by the manufacturer. I believe that the individual dose must be established in every case.

DR. WALTER FREEMAN, Washington, D. C. At St. Elizabeth's we have been using sodium amytal for the purpose of bringing our catatonic patients back into contact with reality. In their catatonic state they are inaccessible and one cannot carry out any satisfactory therapeutic procedure beyond the physical ones. Sodium amytal renders them accessible so that they can discuss their problems and so that the physician can apply the proper therapeutic measures.

DR. ALEXANDER B. MAGNUS, Chicago. Dr. Bleckwenn's assertion that the Wisconsin group was pioneering in prolonged sleep therapy does not exactly correspond with the history of sleep therapy. To Klaesi, who in 1920 systematized the method of producing prolonged sleep credit goes for the work in modern psychiatry. As a matter of fact instances of cures through the induction of a state of stupor in mental patients have been described in the literature since 1870. Bleckwenn, of course, is credited with having started the use of sodium amytal a few years ago. In 1928 I had the opportunity of observing the work of Lutz in Zurich in prolonged sleep therapy with dial and morphine-scopolamine combination. I have since followed this method with some modification. Since the work of Klaesi a number of barbiturates have been tried, most of them meritorious but all of them possessed of some disadvantages. Dial may be classed as one of the slow acting drugs, but I do not fully agree with the objection to the slow acting drugs in narcosustained therapy. The slower or more rapid action is not indicative of the property of the drug as much as of the method of administration. In my work alcoholic and drug addicts and borderline and psychiatric cases were treated. The former were treated for four or five days and the latter two groups for ten days. If properly used and under careful nursing supervision, I consider dial therapy safe. The urinary reduction is frequently encountered. Even if the drug is given in small doses, the average patient will have between three and ten reductions in ten days. Catheterization therefore sometimes becomes a routine procedure. The next important complications to guard against are bronchopneumonia and shock. It would seem that the drug affects directly the capillaries of the bronchial tubes leading to a certain amount of congestion. Preexisting pulmonary conditions, acute or chronic, are important contraindications to the use of barbiturates.

DR. CARL P. WAGNER, Hartford, Conn. I have found sodium amytal the most effective of the drugs. My policy has been, when administering the drug by mouth, to start with the dosage recommended by the manufacturer and then to increase it or decrease it depending on the reaction of the patient. This problem presents itself if the drug is given intravenously, because the action of sodium amytal is so rapid that one can determine how much to give while the needle is still in the

vein. Frequently it is not necessary to give more than 1½ grains (0.1 Gm.) or perhaps 2 grains (0.13 Gm.) of sodium amytal to get the desired response. As an antidote for barbituric acid poisoning I have used coramin but have not had the degree of success described by Dr. Bleckwenn. I used it intramuscularly rather than intravenously. Of course, in the scale of toxicity that has been worked out by Dr. Barlow, dial comes well down the scale as being a relatively nontoxic drug. I prefer to use the shorter acting drugs because I can get the peak of reaction in a short time. When the longer acting drugs are used, the maximum reaction does not occur for an hour or two hours after the drug has been given. This is not the case with the shorter acting drugs. They enable one to control patients a little better although they may be a little more toxic than dial. It was stated that the principal toxic effect of the barbiturates has been on the respiratory system. This is quite true. I have had some experience with the toxic effect on the heart. In one instance a woman aged 60, with a blood pressure of 140 systolic and 80 diastolic, received 1½ grains of nembutal and developed ventricular fibrillation. In regard to respiration, I might add that with the use of the longer acting drug the reaction that has been described as most typical is that of pulmonary congestion and edema, which may terminate fatally. The shorter acting drugs act more directly on the respiratory center and cause death rather suddenly. I have never seen an instance of addiction to barbiturates in the same sense that one becomes addicted to morphine. Patients do develop a tolerance for barbiturates and the use of barbiturates becomes a habit like a good many other things. They can be withdrawn without severe withdrawal symptoms.

COLPECTOMY

HAROLD E. SIMON, M.D.
BIRMINGHAM, ALA.

Colpectomy is an operation which has fallen into an undeserved oblivion in this country largely because it involves the complete anatomic and physiologic loss of the vagina. However, simplicity of performance, safety, uniformly good results, and applicability to conditions not amenable to any of the reconstructive types of operation insure for it a permanent place among useful surgical procedures.

LITERATURE

In Europe, colpectomy enjoys considerable popularity, in America it is seldom employed and the indications for the operation as well as the technique of the procedure and its modifications have received scant mention in the literature. Procedures more extensive and much less uniformly satisfactory are sometimes attempted in patients in whom colpectomy is definitely indicated.

Le Fort¹ in 1876 first described the central type of partial colpectomy for prolapse. His patient, aged 48 years, had a marked prolapse. He performed central colpectomy only at first and obtained a satisfactory result, but he noted relaxation of the perineum and in order to prevent any possible recurrence he subsequently performed a perineal repair. Earlier attempts to treat prolapse of the uterus surgically consisted in narrowing the vaginal orifice anteriorly or posteriorly or in closing the orifice by suturing together the labia. These methods were all unsatisfactory and resulted usually in recurrence.

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

¹ Le Fort, Leon. Nouveau procede pour la guérison du prolapsus uterini. *Bull. gen. de therap.* 42: 337, 1877.

In the French literature, Brocq and Nora,² Dieulafe,³ Dujarier,⁴ Laurentie⁵ and Petit-Dutailh⁶ among others make the operation the subject of complete discussions.

Payne⁷ credits Simon with the original use of total colpectomy in 1885 for intractable vesicovaginal fistula.

In American literature, little reference is made to colpectomy. Baer and Reis⁸ report 14 colpectomies in 212 operations, and Phaneuf⁹ 13 colpectomies in 183 operations for prolapse of the uterus. Others¹⁰ have merely mentioned the operation in a general discussion of prolapse and usually assign it a negligible place among useful surgical procedures.

INDICATIONS

1 Prolapse in the aged constitutes the most frequent indication for colpectomy. In old and debilitated women in whom a short intervention under local anesthesia alone is feasible, this operation offers a maximum chance for cure with little or no risk.

The onset of sexual old age in the female cannot be accurately defined in years. Certainly there could be little objection made to the loss of the vagina after the age of 70, and the menopause would probably mark the limit below which the operation would be contraindicated except under very unusual circumstances. Between these limits the selection of this operation would depend on the social status of the patient, her physical condition, the feasibility of performing some more conservative procedure, and finally, but not of least importance, on the consent of the patient herself after all aspects of the operation have been carefully explained to her.

2 After hysterectomy the recurrence of prolapse with cystocele or rectocele, or both, is tremendously difficult to treat. Fortunately, such recurrences have been encountered with relative infrequency since the abandonment of hysterectomy alone, either abdominal or vaginal for the treatment of prolapse. Supplemented by adequate reconstruction of the pelvic supports, abdominal and vaginal hysterectomy seldom result unfavorably when used within their limitations in the treatment of prolapse.

When preservation of the vagina is a very important consideration, this type of recurrent prolapse may sometimes be successfully treated by the Payne⁷ operation or by fixation of the dome of the vagina either into the abdominal wall as described by Sloan¹¹ or into the pelvic wall on one side as in the Knapp¹² operation supplemented in either instance by anterior and posterior colporrhaphy. Often however, and especially in

older patients, or when other perineal operations have been performed unsuccessfully previous to hysterectomy, the anatomic structures are so distorted and inadequate that any operation less certain than colpectomy to result in cure would be inadvisable.

3 Recurrences after the Watkins-Wertheim interpolation operation for prolapse and cystocele may sometimes be best handled by hysterectomy and colpectomy.

4 Vaginal hernia is rare but should be considered in all cases of prolapse and whenever a mass bulges into the vagina. Phaneuf,⁹ Ward,¹³ Douglass¹⁴ and others state that vaginal hernia is present with prolapse much oftener than is thought and that it is among the most common causes of recurrence after operations for prolapse, others hold that it occurs very infrequently.

Uncomplicated vaginal hernia may be successfully treated by conservative operation.¹⁵ When the hernia recurs after hysterectomy, when intra-abdominal operations are contraindicated on account of age or for other reasons and the hernial defect is too great to be repaired by conservative vaginal procedures, or when the hernia is large and is a part of an extensive prolapse, total or partial colpectomy after ligation of the sac is often the procedure of choice or the only alternative that offers a reasonable prospect of cure.

5 When vaginal hysterectomy is performed for prolapse, efficient reconstruction of the perineum may be impossible on account of marked atrophy or extensive destruction of tissues. If there is not sufficient contraindication to vaginal obliteration, colpectomy as an adjunct is preferable to a perineal reconstruction which would offer little prospect of permanent cure.

6 Prolapse in nulliparous women is often the result of congenitally defective perineal structures. When effective repair cannot be accomplished, or after the failure of conservative surgical procedures as in Shoemaker's¹⁶ patient, colpectomy may be necessary.

7 Payne⁷ states that intractable vesicovaginal fistula was treated by Simon in 1885 by colpectomy. Modern methods of handling these conditions largely preclude the necessity for colpectomy.

8 Vaginal neoplasm is a rare condition when its surgical treatment involves a very extensive denudation of the vagina, complete or partial colpectomy may be useful.

TYPES OF OPERATION

Colpectomy may be total or subtotal.

Subtotal Colpectomy.—The operation described by Le Fort¹ is the classic procedure of this type. It was devised for the treatment of prolapse, the uterus being left in place. It provides for the drainage of the secretions from the uterus and cervix by the formation of a transverse cavity beneath the cervix, which communicates at each end with two laterally placed canals leading to the surface at the vaginal orifice. Such provision for permanent drainage is essential in all cases in which the uterus is left in place, even when the menopause has been passed.

In the Le Fort operation two rectangular arcs, one on the anterior and one directly opposite on the poste-

rior wall of the vagina, are completely denuded of mucosa. The upper limit of each rectangle should not extend beyond a point 2 cm. below the cervix, the lower limit posteriorly corresponds to the mucocutaneous junction, anteriorly it extends nearly to the urethral opening. The width of each rectangle should be such that the mucosa remaining on each side will form a canal approximately 1 cm. in diameter. Bleeding is carefully controlled and the denuded rectangles are then accurately apposed and sutured together from above downward with interrupted catgut sutures. A few strands of silkworm sutures are used for a drain. After the operation is completed, fluid injected into either of the lateral canals should pass upward, across the subcervical space and escape through the canal on the opposite side. A perineal repair when indicated should be performed as a part of the colpectomy. A curettement and any cervical treatment indicated should be performed first.

Total Colpectomy—When the uterus has been removed previously or coincidentally with the operation, provision for drainage is not necessary and the entire vagina may be obliterated.

In the technic described by Dujarier and Larget⁴ and others, a vertical midline incision is made through the vaginal mucosa, from just beneath the urethral meatus, extending over the vaginal dome and down the posterior wall to the midfourchette. The vaginal mucosa is completely removed laterally and the cavity obliterated by suturing together the anterior and posterior walls. A small rubber tube or bundle of silkworm sutures provides drainage from the upper portion of the cavity to the surface.

Numerous objections may be made to this method of total colpectomy.

1 It does not include reconstruction of the perineum, a step very essential for maximum support, as was pointed out by Phaneuf and Brocq. Without reconstruction of the perineum, the direction of the vaginal scar is directly downward, with perineal repair, the direction is more nearly horizontal and provides maximum resistance against intra-abdominal pressure.

2 The lateral fascias and remnants of the uterine ligaments are not utilized to support the bladder, which is allowed to sag back against the rectum. The approximation of the anterior to the posterior wall of the vagina is in the direction of the weakest structures and does not utilize the much stronger and heavier tissues of the lateral walls.

3 The removal of the vaginal mucosa in the directions made necessary from the type of incision employed does not provide maximum ease and accuracy of separation and is opposite in some portions to that which is familiar to the surgeon.

It should be emphasized, therefore, that perineorrhaphy is an essential step when the perineum is deficient and it is suggested that partial anterior and posterior denudation with anterior and posterior reconstruction be done first, then the denudation completed and the cavity obliterated. The operation as modified is not deprived of its simplicity to any appreciable extent and it is made much more efficient.

MODIFIED TOTAL COLPECTOMY

1 Under sacral anesthesia a vertical incision is made through the vaginal mucosa from just beneath the urethral meatus and extended well above the cystocele. The vaginal mucosa is elevated well laterally and two

or three sutures are deeply placed to bring the lateral tissues across beneath the urethra and lower part of the bladder.

2 The posterior vaginal mucosa is elevated, and the levator muscles and adjacent tissues are exposed and sutured together as in the usual perineorrhaphy.

3 The remaining vaginal mucosa is then removed down to the mucocutaneous junction. In the presence of marked cystocele the ureters will drop well downward and backward but will not be easily injured in their altered position is borne in mind. Opening of the culdesac, which may occur at this time, is without danger. Bleeding is accurately controlled by ligatures and hot packs.

4 The cavity is obliterated from above downward by a series of sutures of doubled heavy chromic catgut. They are placed deeply in the lateral structures and include only a very superficial bite in the anterior and posterior walls as they are passed across them. The ureters should be carefully avoided in placing the upper sutures. When these sutures are tied, the lateral walls are approximated.

5 Drainage is very essential to prevent the accumulation of blood within the cavity. Such an accumulation produces an elevation in temperature and pain, and

as it dissects downward to the surface it weakens the scar. This drainage is provided by a small tube or a bundle of silkworm sutures extending well up into the top of the cavity. It is left in place for eight or ten days.

6 After the vaginal cavity is obliterated down to the mucocutaneous junction, the mucocutaneous edges are accurately approximated, the drain is allowed to pass out posteriorly or in the midportion. A retention catheter may be left in the bladder for ten days.

RESULTS

In a series of ninety-two patients on whom various types of colpectomy had been performed by eight different operators, there were no deaths, as shown in the accompanying table. A postoperative hemorrhage occurred in one patient reported by Laurentie and a hematoma in one of Dujarier's patients. One of Phaneuf's patients developed a low grade infection and accounted for the only recurrence in fifty-nine patients who were followed up.

These results are particularly striking when the advanced age and the poor physical condition of most of these patients is considered and in view of the results obtainable by any other type of operation.

SUMMARY AND COMMENT

1 Colpectomy is an operation which is easily performed, yields uniformly good results and is safe. Its

greatest objection is that it involves the functional loss of the vagina but when this is a lesser or not a serious consideration, it is an operation which insures good results with minimum risk in a number of conditions not readily amenable to less radical procedures

2 Colpectomy may be subtotal, as in the Le Fort operation, which permits the uterus to be left in place, or total if the uterus is removed

Simple denudation of the vaginal mucosa and approximation of the anterior to the posterior walls does not provide the most satisfactory operation for total colpectomy and does not accomplish maximum strength for the repair. The inclusion of anterior and posterior colporrhaphy and utilization of the strong lateral tissues for support are of importance

1131 North Twenty Eighth Street

ABSTRACT OF DISCUSSION

DR J C MASSON, Rochester, Minn. I am satisfied that colpectomy is utilized probably in a haphazard or modified manner, much more frequently than the literature would indicate. I frequently have seen large postoperative vaginal hernias that had followed abdominal or vaginal hysterectomy. Adequate support had not been provided at the vault of the vagina, and in many cases no attempt had been made to repair an extensive laceration of the perineum. In many of these cases, any attempt at reconstruction means partial vaginectomy or colpectomy. If the vault of the vagina is fixed into the anterior abdominal wall or to the side of the pelvis, the condition will be helped only temporarily. There will be a definite tendency toward recurrence of the cystocele if the patient is much on her feet. Most of the patients are well past the menopause, and on account of the unnatural dryness and thickening of the vaginal mucous membrane, from exposure and irritation for many months, sexual relations have not been satisfactory and in most cases have been entirely discontinued. The patient raises no objection to radical operation provided there is a reasonable certainty that relief can be obtained from the uncomfortable bearing-down feeling protrusion of the parts, irritable bladder, and difficulty in emptying the lower part of the bowel. The patient and her husband, however, should thoroughly understand, before the operation is undertaken, what the postoperative condition will be. The operation is also indicated in many cases of procidentia of elderly women. It must be remembered that many patients who are 70 years of age are going to live at least ten more years. The operation can be done more quickly and more safely and will result in more relief to the patient than so-called less radical operations that require extensive plastic procedures, or abdominal incisions and the long continued use of a pessary. I have had no experience with the LeFort procedure but if patients are averse to losing any of their organs, if the case is one of vaginal prolapse as a result of congenital weakness of the muscles of the pelvic diaphragm, or if the patients do not contemplate marriage it might be satisfactory. I think however that complete colpectomy as advised by Dr Simon is a better operation and has much to recommend it. The operation can be done satisfactorily in conjunction with application of the Mayo principle of giving support to the bladder after removal of the uterus and in conjunction with high approximation of the levator ani muscles before the attempt is made to obliterate the vaginal canal. I should like to add here however that the reason for post-operative hernias and for recurrence of cystocele and rectocele following the Mayo type of operation is generally the result of the surgeons not having taken sufficient pains to anchor the approximated anterior ends of the broad ligaments under the symphysis pubis and to effect partial obliteration of the cul-de-sac and shortening of the uterosacral ligaments. In general anesthesia is contraindicated this operation can be done with a minimum amount of risk under low spinal anesthesia sacral block or local infiltration. If advisable patients can be allowed to be out of bed in about half the time necessary following the more frequently used operations.

THE PREVENTION OF COMPLICATIONS IN THYROID SURGERY

ARNOLD S JACKSON, M.D.

MADISON, WIS

The prevention of complications, both immediate and remote, following thyroidectomy is a subject of extreme importance to those interested in thyroid surgery. The statistical study of operative records reveals the number of patients who were successfully operated on, but it tells nothing of the patients whose lives perhaps hung in the balance for hours or days. An error in judgment either at the operating table or later may be responsible for the development of complications that greatly alter mortality statistics. Although such a mistake may not result in the death of the patient, it may change his whole future health and welfare.

In perhaps no field of surgery are complications more prone to develop than following operations on the thyroid. This is so true that there are few surgeons who have not experienced most of the unfortunate sequelae at some time during their careers. It has been my misfortune to have run the gantlet and, fortified with this knowledge and experience, I offer the following suggestions.

Complications following thyroidectomy may be divided into three classes: immediate, delayed and remote.

In the first group, immediate complications, are found those accidents which occur at the operating table, they may be listed as follows:

- 1 Injury of the recurrent laryngeal nerve
- 2 Hemorrhage
- 3 Injury or collapse of the trachea
- 4 Air embolism
- 5 Acute hyperthyroidism
- 6 Anesthesia complications

The second group, delayed complications, is as follows:

- | | |
|-------------------------------|------------------------|
| 1 Tetany | 9 Tracheal obstruction |
| 2 Hemorrhage | 10 Anoxemia |
| 3 Hyperthyroidism | 11 Hematoma of wound |
| 4 Tracheitis | 12 Mania and psychosis |
| 5 Pneumonia | 13 Shock |
| 6 Cardiac failure | 14 Glycosuria |
| 7 Wound infection | 15 Embolism |
| 8 Temporary nerve involvement | |

The third group, remote complications, includes:

- | | |
|------------------------------|-------------------------------|
| 1 Persistent hyperthyroidism | 5 Skin adhesions |
| 2 Recurrent hyperthyroidism | 6 Hypothyroidism and myxedema |
| 3 Cardiac failure | |
| 4 Tetany | 7 Progressive exophthalmos |

Obviously, in this short dissertation it is impossible to dwell in detail on any save the most important of these problems.

IMMEDIATE COMPLICATIONS

1 During the past four years it has been my good fortune to have avoided successfully injury to the recurrent laryngeal nerve. Few surgeons performing any number of thyroidectomies have avoided injuring one or even both nerves at some time in their experience.

From the Jackson Clinic
Read before the Section on Surgery, General and Abdominal at the
Eighty-Fourth Annual Session of the American Medical Association
Milwaukee, June 14, 1933

The most frequent causes of this in their order of importance are the placing of hemostats too low on the lateral borders of the gland, and, likewise, on the lower poles, too great haste, a wet operative field obscured by numerous hemostats, substernal and intrathoracic goiters with distortion of the anatomy, and ligation of the inferior thyroid artery too close to the gland. The greatest care should be used in placing hemostats on the lower lateral and inferior poles preparatory to resecting the gland. Probably, however, the majority of nerve injuries occur after the surgeon has begun resecting the gland, particularly in that type which is extremely friable and vascular. In an effort to secure hemostasis, the friable gland crumbles away and a comparatively simple operation suddenly becomes a serious one. Hemorrhage must be controlled and, at the same time, injury to the nerve avoided. The failure of the surgeon to place his hemostats sufficiently high on the lateral walls at the start accounts for the majority of complications in thyroid surgery. If the gland is resected from within, leaving only a thin but sufficiently deep outer shell not only will nerve injury be avoided but hemorrhage from within the capsule can always be controlled.

2 The most frequent cause of serious hemorrhage results from the tearing of the lateral or middle thyroid veins in elderly persons with substernal goiters. Experience teaches one to be on guard for this dangerous sequela. As soon as possible these veins should be isolated and, if necessary to elevate the goiter they should be ligated and divided at once. The method of running the index finger down along the lateral and inferior border of the goiter in order to free adhesions and to elevate the goiter should be avoided, as occasionally a friable vein will be caught and torn by the finger. Rather the goiter should be elevated by careful traction, the capsule being dissected with the scalpel, and the veins being ligated as they are encountered. If three hemostats are placed on the superior thyroid artery and vein and they are divided between the second and third and immediately sutured with number two plain gut, these vessels will cause little concern. Serious bleeding from within the capsule can be controlled with the index finger pressing upward and inward along the lateral border of the gland.

3 Injury to or collapse of the trachea is seldom serious and may be avoided by careful and not too rapid dissection in a dry field. In our clinic, two fatal cases of collapse of the trachea occurred preoperatively within the past year. This was a most unusual and new experience, but it proved to me that such complications may occur following operation and are not necessarily dyspnea resulting from nerve injury. In one of our cases the trachea collapsed a few minutes after the patient was admitted to the hospital and before a tracheotomy could be performed. The other occurred on the table just before operation, and although tracheotomy was performed at once, the patient lived only a few hours. Both patients had large intrathoracic goiters.

4 I have seen four cases of air embolism, two of which occurred in my service, with a single recovery. As one patient was being taken from the operating room, she suddenly coughed violently and tore loose a ligature on the anterior jugular vein. Although the dressing was immediately removed and the wound reopened, she died in a few seconds. The second case occurred while an attempt was made to locate the source of a delayed hemorrhage. In this instance the patient's

head was immediately lowered and oxygen with carbonyl dioxide administered. She remained unconscious for seven hours and recovered with a partial hemiplegia that later cleared up. The absence of valves in the thyroid veins and their tendency to remain patent makes it important to ligate every vessel carefully.

5 Acute hyperthyroidism on the table was a common complication before 1922 but has been rare since the advent of compound solution of iodine. Proper preoperative preparation should avert it but if it occurs the operation should be stopped and the patient brought under control with iodine, ice bags and fluids in his room.

6 It has been my good fortune to have had but one serious complication that I might attribute to the anesthetic: this was in a case of pneumonia. Some years ago procaine hydrochloride reactions occasionally occurred, but with the development of the superficial nerve block method and with the preoperative use of 10 grains (0.6 Gm.) of sodium barbital this complication has been eliminated.

DELAYED COMPLICATIONS

During the past seven years I have not seen a case of tetany. Experience taught me that tetany as well as nerve injury resulted largely from dissecting too far down the lateral walls of the gland. Leaving a sufficient shell of gland and capsule will prevent tetany.

Delayed hemorrhage may occur as late as one month following operation and is usually the result of a low grade wound infection. Hemorrhage the second or third day, however, is the result of improper hemostasis.

Sufficient iodine by mouth, by duodenal tube, by rectum or by vein fluids, ice bags, sedatives, oxygen, good nursing and psychology will usually control hyperthyroidism.

Tracheitis is prevented by careful operative technique in avoiding trauma of any sort to the trachea and by the use of a steam tent, codeine and atropine. In elderly persons it is safer to perform a two-stage operation.

Cardiac failure remains the most serious sequela in long-standing cases of toxic adenoma and exophthalmic goiter. The controversy still persists as to whether digitalis does harm or good in the preparation and after-care of the former. Some of us believe that we have saved many lives with digitalis, Plummer and others feel they have saved lives by not using it.

Wound infection, when it occurs, is most annoying because it may take weeks to clear up. Fortunately it is rare and in my experience is less often seen when no drainage tube is used. Allowing serum to collect for a day or two without probing will often invite trouble.

Temporary involvement of the nerve may occur as a result of edema of the tissues or trauma, but it is seldom of serious import.

Much could be said about tracheal obstruction and anoxemia and about their prevention and treatment with oxygen therapy. I have saved several critical cases with the oxygen tent or merely by inserting a nasal catheter and connecting it with an oxygen tank.

Mania and psychosis are occasionally serious and even fatal sequelae of thyroidectomy. I know of no way of anticipating or avoiding these conditions, and their treatment is largely that of a psychosis from other causes.

The avoidance of postoperative shock has been ably elaborated on by Crile and needs no further mention here.

All goiter cases should be carefully examined preoperatively for the possibility of glycosuria. Occasionally, a true diabetes but more often an acute glycosuria will be precipitated by thyroidectomy.

REMOTE COMPLICATIONS

I have seen tetany develop as late as eight months after thyroidectomy.

In burned out cases of exophthalmic goiter or in advanced toxic adenoma, cardiac failure is apt to occur in from one to five years following thyroidectomy.

Rarely in this surgical age is postoperative myxedema encountered, although mild grades of hypothyroidism are observed and even desired by some surgeons.

Recurrent hyperthyroidism remains the most frequent and serious remote postoperative complication, or, rather, persistent hyperthyroidism, because this condition usually but not always results from a failure to remove sufficient tissue at the time of the first operation. The frequency of recurrence runs as high as 5 per cent even at the best thyroid clinics. In some instances, several recurrences develop in a single patient.

Sufficient time has not yet elapsed, but during the past three years I have found a method that more nearly solves this problem of recurrence than any other that I have yet tried. With but a single recurrence during this period I have not been tempted to consider denervation of the suprarenal glands, as advocated by Crile. The advent of electrosurgery has in my opinion revolutionized the technique of thyroidectomy. Not only is it possible to remove more thyroid tissue with a greater degree of safety than with the scalpel, but it is possible to coagulate all but a small fraction of the remaining gland, thus producing fibrosis and scar tissue and permanence of cure. Strangely enough, myxedema does not develop, but the patient proceeds to a normal convalescence with greater rapidity.

To prevent persistent and recurrent hyperthyroidism, a careful postoperative regimen should follow, with iodine for six months, high caloric diet, permanent restraint from stimulants and proper rest. Likewise, in all cases of exophthalmic goiter, septic tonsils if present should be removed some months after thyroidectomy. Electrosurgery, however, has been the most important factor in overcoming this most serious indictment of thyroid surgery.

CONCLUSION

One cannot improve on the words of Dr. Charles Mayo, who stated that exophthalmic goiter should never be considered as an emergency operation. Thus with a careful preoperative preparation and with the avoidance of undue haste in operating, the majority of complications in thyroid surgery will be prevented.

16 South Henry Street

ABSTRACT OF DISCUSSION

DR. ROBERT S. DINSMORE, Cleveland: There are several well established facts about thyroid surgery. There has been established a low mortality rate in all large thyroid clinics. Generally speaking the results of thyroid surgery are excellent. There is however as Dr. Jackson has pointed out a low residual morbidity rate which can be markedly lowered by the prevention of complications. Dr. Jackson has divided these into three groups and I feel that by far the most important are the early or the immediate complications. If one avoids a postoperative hemorrhage or injury to the recurrent laryngeal nerve or parathyroid bodies the morbidity rate will be fairly low. In case of severe hemorrhage one should take the operat-

ing team back, give the patient a light anesthetic and carefully enucleate the hematoma. The most distressing type of postoperative hemorrhage is one that comes from the inferior thyroid artery following the removal of an intrathoracic goiter. If after the removal of a large intrathoracic goiter a fixed cavity is formed the case should be treated by a secondary closure. It is quite true that most of these cavities are quickly obliterated by the lungs and the pleura but occasionally a large cavity extending well down into the chest will result. Extravasation or venous oozing into this cavity may take place with no outward or visible symptoms in the neck. The patient, however, will become very pale, the pulse will become very rapid, and there will be a slight widening of the mediastinal dulness. The extravasation may extend into the posterior or anterior mediastinum but almost invariably the result is fatal. The heart simply becomes strangulated. There is another rare type of postoperative hemorrhage that is occasionally seen. On the third or fourth day after a thyroidectomy, the patient may develop a slightly brassy character to the voice, and the laryngeal examination will show an extravasation into one of the cords. This is not a complication that causes any trouble, as it usually clears up in a few days. I have had less trouble with the recurrent laryngeal nerves in cases in which I have dissected the gland from the outside, placing the clamps on the lower pole so that they stand erect in the wound, and placing the clamps on the superior pole from within outward. Dr. Jackson mentioned that the delirium of acute hyperthyroidism should be differentiated from the true manias or the psychoses. In all the cases of major psychoses that I have seen after an operation, the psychiatrist has been able to establish the fact that the patient had a previous psychosis in addition to the hyperthyroidism. The two points of importance about a patient with a major psychosis and hyperthyroidism are, first, that these patients should not be operated on near one of the acute exacerbations and second, that a guarded prognosis should be made as to the course of the psychosis. I believe that most of these patients present two separate clinical entities and that the psychosis does not follow the hyperthyroidism but that it is a major psychosis and hyperthyroidism.

INSULIN IN THE TREATMENT OF TUBERCULOSIS

FREDERICK M. ALLEN, M.D.

NEW YORK

The work summarized in this paper comprises more than eighty nondiabetic tuberculosis cases. Several New York tuberculosis specialists kindly referred volunteers from their charity services to receive the first treatment in Morristown, and Eli Lilly & Co., furnished insulin for this purpose. A preliminary announcement was previously published.¹ The observations were then extended in two parts which will be published in detail in separate papers. One of these comprised a series of twenty-six cases studied in the Valley View Sanatorium, Paterson, N. J. in collaboration with Drs. William E. Pottinger, Stephen A. Douglas and Earl Warren. The second comprised forty-five cases observed in the City Hospital Welfare Island, New York City in collaboration with Dr. James S. Edlin.

This work was a natural development from certain studies of diabetes. On the practical side I² was apparently the first to publish observations on the use of insulin in diabetic cases complicated with tuberculosis. Numerous authors since then have confirmed the fact that the results in such cases are revolutionized by insulin and the higher nutrition which it makes

Read before the Section on Pharmacology and Therapeutics at the Fifty-fourth Annual Session of the American Medical Association, Atlantic City, June 1, 1933.

1. Allen, F. M. J. M. Soc. New Jersey 20: 315 (April) 1932.
2. Allen, F. M. J. Medical Research 2: 534-543 (1933).

possible. Historically, the greatest numbers of tuberculosis cases and deaths among diabetic patients occurred under the earlier crude forms of treatment when the sugar was not controlled. The control of the sugar brought some degree of improvement, even though accomplished at the price of undernutrition, but the results nevertheless were highly unsatisfactory and the prognosis was usually bad. The revolution accomplished by insulin treatment has been such that I myself feel that the diabetic patient, properly treated, has a somewhat better chance than the nondiabetic patient with the same degree of tuberculosis. At any rate, the history of diabetic treatment seems to confirm the prevailing views concerning the importance of nutrition for resistance against tuberculosis.

On the theoretical side, I have since 1914 been publishing experimental and clinical evidence to prove that the internal secretion of the pancreas is related not merely to carbohydrate metabolism but to total metabolism and body weight. The first observations, made by comparisons of higher and lower diets, were confirmed after insulin was discovered by showing that the difference between high and low body weights in diabetic patients can be definitely measured in terms of insulin requirement. Reducing the body weight under other-

Chart 1—Prolonged storage of insulin in a 5.6 kg dog receiving one dose of 2000 units of insulin subcutaneously and successive intravenous injections of 10 Gm of dextrose.

wise constant conditions reduces the insulin requirement, and any marked increase of body weight is the most powerful means of increasing the insulin requirement. Insulin may therefore be regarded as a specific anabolic hormone. Moreover, the notoriously poor resistance of depancreatized animals and untreated diabetic patients to many infections demonstrates the importance of an adequate supply of insulin for normal resistance. Whether any raising of resistance is possible by a particularly liberal supply of insulin, in other words by administering insulin to nondiabetic patients, is a question to be decided. An analogy may be suggested with the administration of surplus quantities of vitamins for improving the resistance to tuberculosis. There are also reports in the literature favoring the use of insulin for other types of infections.

The first use of insulin for building up weight in nondiabetic patients was by Pittfield,³ Marriott⁴ and Barbour⁵ in 1923 and 1924. The first trial of insulin in nondiabetic tuberculosis cases was by Bauer and Nyiri⁶ in 1925. Since then a large literature has grown

up on this subject. Nearly all the European authors have used insulin in comparatively small doses for comparatively brief "fattening cures." Falta⁷ has rendered service in attracting attention to various phases of this subject, though he cannot be credited with priority. The belief has also been widely disseminated that insulin is suitable only for inactive tuberculous cases and that its use is contraindicated by active lesions, fever, hemorrhage and other complications. More recently, some authors have increased the dosage to 60 units a day or more and have extended the treatment either continuously or at intervals over several months. To Leggett and Callahan⁸ seems to belong the credit for most definitely breaking away from the old idea of "courses of insulin" and using insulin in dosage suited to the individual need and for the periods that seem individually advisable, sometimes for from three to six months.

As the processes of nutrition are so complex and obscure, theories should not venture far beyond proved facts. Insulin is evidently only one of many factors governing both appetite and nutrition. Hyperinsulinism is not necessarily synonymous with either hunger or obesity. Insulin or hypoglycemia may sometimes be accompanied by nausea instead of hunger. This reversal of rule is commonest in toxic states, but on the other hand some patients with fever and intoxication may respond to insulin with appetite and gain in weight, while some who are not toxic may develop no hunger and cannot be fattened with insulin. Before undertaking the work with human patients it seemed necessary to perform animal experiments concerning the possible toxicity of insulin and also the possibility of keeping the organism enriched with insulin. The observations of previous writers on the former point are not definitive. It is not safe to regard insulin as nontoxic in absolutely unlimited dosage, but, on the other hand, doses much higher than were ever needed in tuberculosis treatment can be given with no bad effects beyond what can be antidoted by moderate quantities of carbohydrate.

Physicians are inclined to regard the effects of insulin as limited to a few hours, but I⁹ have shown that, with large dosage, prolonged storage of insulin is demonstrable. Chart 1 illustrates these experiments, which will be reported in greater detail later. When such a small animal as a 12½ pound (5,670 Gm) dog receives such a large dose as 2000 units of insulin, protection from hypoglycemic symptoms requires no enormous dosage of carbohydrate but only 10 Gm at a time. The chief difference is that these protecting doses of dextrose must be continued for a day or two during which time there is evidently an excess of insulin stored in the body. These experiments illustrate not only the feasibility of artificial hyperinsulinism but also the fallacy of attempted ratios between carbohydrate and insulin, and other theoretical matters. The general principle that the combating of insulin shock depends less on the total quantity of carbohydrate than on the frequency of its administration will be found very valuable practically in the insulin treatment of both diabetes and tuberculosis.

In general, I have administered more insulin than has heretofore been given to nondiabetic persons, in the sense of the size of doses and the length of treatment. One man received 320 units a day with rapid

gain of weight, but this was an exception. Treatment was usually begun with 5 units before each meal and increased to about 40 units three times a day, but individualization should be emphasized as the chief principle. There are individual peculiarities of insulin tolerance. Women are apt to take less than men. Toxic patients usually do not stand as large doses as the nontoxic, contrary to the rule in diabetes. The same individual may differ in his insulin requirement at different times. When small doses are unsuccessful, large doses will sometimes give results and vice versa. When a patient has flourished for several weeks or months on a certain dosage and has perhaps reached

regulation of calories. The others were automatically inhibited by the nausea and other symptoms previously mentioned. One question considered was whether the carbohydrate tolerance would change by reason of either stimulation or disuse atrophy of the patient's own pancreatic islands. With numerous dextrose tolerance tests we have confirmed the observation of some former authors that abnormally high results are rather common in tuberculosis. The accompanying table illustrates some of these figures and also the fact that they are apt to become considerably higher during the course of insulin treatment. Later tests showed however, that this is a temporary peculiarity passing off within a few days after discontinuance of the insulin, and in no instance has there been any evident tendency to the development of diabetes or any other endocrine disorder.

normal or slightly more than normal weight, he may begin to show sensitiveness in the form of insulin reactions or nausea and may continue to thrive only after the dose has been cut perhaps in half. The best results require study of such details, also training and skill in this particular method. The administration of insulin has thus been continued over eight months. The kind and quantity of the diet is also planned to suit the individual, but commonly a mixed diet containing liberal carbohydrate may be given, consisting of not only the usual three meals but also lunches between meals and at bedtime.

In character, the cases ranged from mild to moribund. Exact data can be given only in the detailed reports, but the majority were severe, active and febrile. The City Hospital work was hampered by lack of suitable control periods, the treatment in most cases being begun soon after admission and the results judged only by the general experience of the tuberculosis specialists with such cases. In the Valley View Sanatorium there was the advantage of prolonged and complete preliminary observations for comparison with the subsequent results under insulin. One general conclusion was that in a broad clinical sense insulin properly used is harmless. Reactions are usually easy to prevent and harmless if they occur. Fever is by no means a contraindication, though in far advanced cases the disturbances of insulin injections and increased feeding may elevate the temperature somewhat and thus be undesirable. Hemorrhage also need not be a contraindication except in a minority of sensitive cases, and some very good results have been obtained in this type. Rarely, urticaria or other symptoms may prove troublesome even to the extent of stopping the treatment. Intestinal lesions are more often an indication than a contraindication for insulin.

The administration of insulin to nondiabetic patients in such quantities and for such periods is an experiment in itself and a watch has therefore been kept for possible endocrine effects. Only one patient displayed any tendency to become too fat requiring artificial

The most striking and obvious clinical result in a case of suitable type is a gain in appetite, weight, strength and spirits. This result is apt to be greatest in the mild or quiescent cases and to be less in proportion as fever and intoxication are greater but there are exceptions in both directions. A general summary is not very useful because of individual variations. Taking the City Hospital series for illustration, the forty-five patients showed an average gain of 25 pounds (11.3 Kg), ranging from a minimum of 3 pounds (1.4 Kg) to a maximum of 29 pounds (13.2 Kg) in females, and from a minimum of 5 pounds (2.3 Kg) to a maximum of 54 pounds (24.5 Kg) in males. In two cases there was weight loss of respectively 2 and 6 pounds (0.9 and 2.7 Kg) with insulin. Except in the very advanced cases, the weight and strength gained under insulin were entirely or largely retained after the insulin was stopped.

Chart 2 illustrates two of the best results in the Valley View Sanatorium series. The solid line represents the weight of a young woman, aged 26, with far advanced bilateral tuberculosis, severe cough and pro-

fuse expectoration, temperatures of from 99.6 to 100.6 F, and a complication with violent attacks of sinusitis with daily purulent discharge. Other symptoms were severe headaches, flatulence, gnawing sensations in the abdomen, nausea and vomiting (diagnosis of hyperacidity and duodenal ulcer), general malaise, weakness, loss of weight and toxic appearance. During three months in the hospital downward progress in all these respects was demonstrated. The establishment of artificial pneumothorax on the left side did not bring any clinical improvement. With the beginning of insulin there was an immediate change. The indigestion and abdominal symptoms disappeared almost completely. The attacks of sinusitis subsided though some purulent discharge persists. The gains in strength, spirits and

general comfort correspond to the gain in weight. The x-ray reports seem more encouraging but must be confirmed by longer time.

The broken line represents the weight of a man, aged 22, who had been under observation for six years and in the hospital one year. He appeared greatly improved following phrenic section, but on transfer to the ambulant ward preparatory to discharge he had a serious breakdown with increase of cough and sputum, temperatures of from 100 to 101 F, lack of appetite and strength, and loss of 20 pounds (9 Kg), the condition being such that his death was expected soon. Under insulin treatment there was gain of strength and spirits corresponding to the gain in weight, the temperature fell and the sputum diminished. The improvement shown by roentgenograms was also very marked.

These examples are given only to illustrate the best results, and there are all other gradations from partial success to complete failure. I shall not go further into the clinical results, because this paper is intentionally written from the standpoint of metabolism. I shall therefore draw only one conclusion, namely that in a large proportion of tuberculosis cases ranging from quiescent to severe, the proper use of insulin can produce marked gains of weight, strength and spirits. Any further conclusions must be drawn with the aid of the tuberculosis specialists in the papers in which they collaborate. It is clearly recognized and has been emphasized from the beginning of this work that insulin is not a specific antibody or a cure of tuberculosis and is not expected to save illicitly hopeless cases. On the other hand it may be permissible to state that the tuberculosis specialists engaged in this work have gained the impression of a beneficial effect of insulin as judged by clinical and laboratory results, and this interpretation appears plausible in view of the generally accepted importance of nutrition in tuberculosis.

45 East Sixty-Second Street

ABSTRACT OF DISCUSSION

DR F. F. CALAMIAN, Pokegama, Minn. I have been using insulin in the treatment of tuberculosis for four years. My attention was attracted to this treatment because of good results obtained in cases of combined tuberculosis and diabetes. Before insulin was discovered I felt that practically all cases of moderate severity with this complication were hopeless. After beginning to use insulin I found that diabetic patients handled their tuberculosis just as well as others of the same degree of severity. The dosage that I use is much lower than Dr. Allen's. I start with 3 units half an hour before meals and increase the dose slowly but have never given more than 15 units three times a day. The best results have been obtained in undernourished patients with anorexia and little or no fever. My experience in cases of acute tuberculosis presenting high fever has been disappointing. It is possible that a larger dose in some of these cases would prove helpful. A few patients with normal blood sugar showed traces of sugar in the urine during insulin treatment. I have been unable to account for this reaction. I agree with Dr. Allen that insulin is not a specific in tuberculosis. It has very definite limitations in the treatment of the disease but many cases are greatly benefited by its use. I think also that cases of anorexia and malnutrition due to other organic diseases should have the benefit of a course of insulin when they do not respond to other treatment. A man, 25, admitted with bilateral tuberculosis after twenty months' treatment in another sanatorium had a pneumothorax with typical signs of tuberculosis of the larva and cecum. He had been failing steadily. His physician suggested thoracoplasty, we compromised by changing from pneumothorax to oleothorax. In a few weeks the pus had disappeared from the left pleural cavity and there was definite improvement in

the contralateral lung. He gained weight very slowly until he was started on 5 units of insulin three times a day, the dosage being increased to 8 units. In a year he had gained 40 pounds (18 Kg) and all symptoms of active tuberculosis had disappeared. He is still doing well.

DR F. M. POTTENGER, Monrovia, Calif. There is a certain type of patient who does not make satisfactory improvement under the ordinary regimen. These patients are often poor eaters even when well and fail to gain on a regimen that fattens the average patient. This is the type which in my hands has gained most from the use of insulin. It has been my experience that patients with tuberculosis show a greater tendency to urticarial reaction to insulin than do the nontuberculous patients and those with diabetes. I should like to know whether this conforms with Dr. Allen's experience. Another interesting experience noted was that of a local degeneration of the muscles following the use of insulin. This did not occur at the point of injection but in distant areas. It was most marked in the gluteal muscles. Two patients were given from 15 to 30 units a day in three doses twenty minutes before each meal. Both patients gained in weight. One gained from 83 to 120 pounds (37.6 to 54.4 Kg), and the other from 110 to 122 pounds (50 to 55.3 Kg). The degeneration in the two patients was so marked that it showed as a distinct furrow in the gluteal muscles. I also noticed in these patients a slight degeneration of the leg and arm muscles. I had difficulty in finding an explanation of the phenomenon. I had been of the impression that tuberculous patients have a low sugar tolerance. I have noticed that those who are acutely ill do not seem to take the normal amount of sugars and starches if allowed to follow their own inclination. I attempted to increase their sugar intake but found that they had an aversion to it. After a little while, however, on forced sugar intake the degeneration disappeared. There is no doubt that insulin will aid in putting on weight and probably at the same time in building up the general resistance of the tuberculous patient who is naturally under weight or who fails to gain under the ordinary regimen. In certain instances it seemed that the insulin was not only of value in putting on weight but that it also improved the pulmonary condition. Whether this was true or not could not be readily proved. It is very difficult to assign the exact part which any measure plays in the treatment of a tuberculous patient for one does many things each of which may help in a limited way.

DR E. S. NICHOL, Miami, Fla. I suppose, since no follow up was given by Dr. Allen that most of these cases have been treated somewhat recently. It is unfortunate that more of a picture of the after-phase of these cases cannot be obtained. My experience with insulin in tuberculosis is small compared with Dr. Allen's group but in the general group of non-diabetic patients with constitutional leanness, malnutrition or asthenia it has been fairly extensive. I found that insulin was provocative of good appetite and had a typical reaction. Until two years ago there were some sixty or seventy papers published on the use of insulin in this type of case but no author reported a follow up to show how long the nutritional gain lasted. I attempted such a follow up two years ago and reported sixty-three cases at the meeting of the Southern Medical Association in New Orleans. Many of the patients were followed from one to five years. Approximately 20 per cent of these patients maintained the weight gained, most of them losing their gain during the first year. So far as tuberculosis is concerned I have yet to find a carefully controlled experiment in which insulin was given along with other sanatorium treatment and then followed up over a long period.

DR MOSES BARRON, Minneapolis. I have used insulin treatment of undernourishment now for a number of years in a manner similar to that described by the author. I had the opportunity of seeing the first cases treated by Bauer and Falta in Vienna in 1926 and was impressed then with the good results obtained. I have recently reported a series of thirty cases treated with insulin. I have obtained good results in 75 per cent of the cases. Most of the patients have retained their weight though some of them did fall back. My series included instances of undernourishment in adults who were non-tuberculous. I am much impressed with Dr. Allen's excellent results. These cases demand a careful follow up in order to decide the final results. In my cases I give fairly large doses.

I begin with 5 units three times a day about half an hour before meals and increase by 1 or 2 units three times a day until an average dosage of 25 units three times a day is reached. My largest dose has been 35 units three times a day. I have had no experience with dosage as large as 200 or more units a day. Offhand, these seem like very massive doses, and still they result in no insulin reaction. I have had no serious reactions in my cases. The present discussion is of great interest, since it shows that insulin is effective in undernourishment even in such specific infectious diseases as tuberculosis during the active stage of the disease.

DR WILLIAM S. COLLENS, Brooklyn. A well known physiologic fact is that the removal of the suprarenals will sensitize the animal to insulin. Cannon has definitely demonstrated that, following a unilateral suprarenalectomy in a cat and the removal of the medulla of the opposite suprarenal, the animal will become so sensitive to insulin that approximately one fortieth of the dose of insulin is necessary to produce the same effect as is produced in the same animal before the suprarenal operations. It becomes necessary, therefore to speak a word of caution in connection with the use of insulin in tuberculosis even though the clinical results are apparently very striking. In illustration of the point in question, a Negro, aged about 50 with a very active bilateral pulmonary tuberculosis running a febrile course was given insulin. As little as 5 units produced very violent hypoglycemic reactions, necessitating the cessation of insulin therapy after five doses. The patient died two weeks following this treatment and the post-mortem examination disclosed almost complete destruction of the suprarenals.

DR FREDERICK M. ALLEN, Morristown, N. J. Insulin was administered in the widest possible variety of cases in order to see its effects, not to recommend it as a routine measure. Gains of weight and appearances of clinical improvement were obtained in some cases of the type which according to most authors are not suited for insulin treatment. The fact remains that insulin is not expected to cure hopeless cases, and the greatest and most lasting results are found in the milder and less toxic types. Dr. Callahan has reminded me that when the insulin prepared from hog pancreas causes urticaria, insulin especially prepared from beef or other species may not do so. Only two treatments have had to be stopped on account of urticaria. In violent attacks, injections of epinephrine hydrochloride may be useful for temporary relief. Evidently there is greater sensitiveness among the tuberculous than among other patients and urticaria is therefore a more important problem with them. The atrophy of tissues is a rarity and I do not know the reason for it. The observations of Leggett and Callahan are among the longest while those that I have reported extend over eighteen months. The longest continuous use of insulin in any individual of this group was eight months. Detailed publications will show that the weight gained with insulin is as a rule well retained except in cases which are too severe or toxic. Individualization of the dosage should be emphasized. The giving of 320 units a day was merely to demonstrate the harmlessness in a favorable case. The dosage usually begins with 5 units and increases to 30 or 40 units three times daily but experience is desirable for adjusting the insulin to the individual need instead of following any arbitrary rule. As I have tried to make clear from the outset, insulin is not a cure for tuberculosis but only an aid to the treatment. It is not suitable for all cases and will not save hopeless ones. In some quarters there seems to be a doctrine that patients with a certain progressive type of lesion or a certain lack of resistance will die regardless of treatment while others with a less dangerous form of infection or with adequate resistance will get well. In an extreme application this doctrine would mean discarding all treatment known up to the present. Neither abundant food nor climate nor bed rest nor pneumothorax can cure tuberculosis or are inherently hopeless cases. It is difficult to prove conclusively that vitamin diets affect the mortality. Nevertheless, all these measures are in practical use and are universally believed to be beneficial. The tuberculo specialists in our group believe that insulin deserves a place in this list for use in selected cases because of its effect in improving nutrition and possibly otherwise altering the soil on which the tuberculous infection develops.

Clinical Notes, Suggestions and New Instruments

ACUTE EDEMA OF THE LARYNX COMPLICATING MEASLES

KENNETH S. OLIVER, M.D. AND EDWARD L. TURNER, M.D.
BEIRUT, SYRIA

Acute edema of the glottis occurring during measles is mentioned as a rare complication by several authors. Barnhill¹ states that acute edema of the larynx sometimes follows or accompanies the worst types of exanthems. Coakley² lists measles as one of the causes of edema of the larynx. Morse³ states that severe inflammation of the larynx is an occasional complication of this disease in children. Scheppegrell⁴ states that 'acute laryngitis is sometimes simulated by the initial stage of an attack of measles. This may become so severe that a tracheotomy is required to relieve the danger of suffocation. As the edema of the larynx is usually relieved by the development of the rash, the operation should be deferred as long as possible and if necessary intubation given the preference.'

REPORT OF CASES

Last winter we saw three cases of acute edema of the larynx as a serious complication during an epidemic of measles in Beirut, Syria. Because of the fact that this complication is relatively rare and, when present usually appears before the eruption, we feel that the cases are worthy of presentation.

CASE 1—T. H., a boy, aged 7 years, admitted to the hospital, Jan. 22, 1933, complained of difficult respiration and cyanosis during the past two hours. About ten days before, the patient had a mild chill followed by cough, headache and photophobia. On the fourth day of his illness a typical measles rash appeared. He was seen for the first time by one of us (E. L. T.) after the rash had appeared. Treatment was outlined and the condition progressed satisfactorily for the next six days. January 22 while playing with his toys in bed he suddenly began to cough and have difficulty in breathing. The parents paid no attention to it at first but within thirty minutes the child had become cyanotic, was coughing violently and breathing with a very loud stridor. A physician was called (E. L. T.) and the diagnosis of acute edema of the larynx made. The child was wrapped in blankets and brought to the hospital about three blocks away where a tracheotomy was performed immediately. As soon as the tracheal tube was in position he began to breathe easily and his temperature, which was 38.5 C (101.3 F) on admission dropped to 37 C (98.6 F) within twenty-four hours. The remainder of his illness was uneventful. The tracheal tube was removed, January 27 and the child was discharged in good condition, January 28.

CASE 2—M. H. B., a boy, aged 4 years, admitted to the hospital Feb. 16, 1933 complained of increasing difficulty in respiration during the past three days. The child had been ill for thirteen days previously. Three days after the onset a typical measles rash developed. The rash had begun to disappear, when the parents noticed that the child was having increasing difficulty with respiration. His voice became hoarse, the respiratory difficulty increased, a stridor was audible and the child was cyanotic. He was brought to the hospital by his family physician and a tracheotomy was performed because of the laryngeal edema. The temperature on admission was 41 C (105.8 F). Twenty-four hours after the tracheotomy the temperature had fallen to 38 C (100.4 F). The child's condition became complicated by a severe cervical adenitis and on February 27 the temperature reached 39.7 C (103.4 F). February 28 pus was aspirated from a fluctuating swelling on the left side of the neck. The abscess was incised March 1 and the pus evacuated. The pus contained gram-negative fusiform

bacilli, abundant small gram negative coccobacilli and diphtheroids. Following this incision the condition of the child rapidly improved. The tracheotomy tube was stopped completely, March 9, and the child was discharged in good condition, March 17.

CASE 3—E. T., a girl, aged 3 years, admitted to the hospital, Feb. 23, 1933, had been ill with a typical attack of measles several days prior to admission. She was brought to the hospital with marked respiratory stridor from acute edema of the larynx. The child was markedly cyanotic and the temperature was 41 C (105.8 F). The entire neck and chest were edematous and the measles rash was still visible. Immediate tracheotomy was performed but the child's general condition was so bad that she died eight hours later.

SUMMARY

Three cases of acute edema of the larynx complicating measles occurred during an epidemic of measles in Beirut during the winter of 1932-1933. Two of the patients recovered following tracheotomy, while the third one died. All three cases developed several days after the rash had appeared and not during the earlier prurash stage as is reported in most of the literature.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

Statement of the Council on Pharmacy and Chemistry on Hospital Formulary

INQUIRIES CONCERNING HOSPITAL FORMULARIES AND THE PROBLEM OF PRESCRIBING IN HOSPITALS ARE RECEIVED BY THE SECRETARY FROM TIME TO TIME. A SYMPOSIUM ON HOSPITAL PRESCRIBING WAS HELD IN 1930 (THE JOURNAL, APRIL 26, 1930, PP. 1277-1284). RECENTLY A COMMITTEE ISSUED A FORMULARY FOR THE NEW YORK HOSPITAL AND AN ARTICLE BY ROBERT A. HATCHER AND WENDELL J. STAINSBY WHICH DISCUSSES SOME OF THE MAJOR PROBLEMS OF THE HOSPITAL FORMULARY WAS PRESENTED AT THE RECENT MEETING OF THE AMERICAN PHARMACEUTICAL ASSOCIATION. THE PLAN OUTLINED IN IT IS IN HARMONY WITH THE IDEALS OF THE COUNCIL WHICH HAS THEREFORE AUTHORIZED PRESENTATION OF THIS PAPER AS A DISCUSSION OF ONE PLAN FOR DETERMINING THE TYPE OF PREPARATIONS ESSENTIAL IN HOSPITAL PRACTICE. THE ENDORSEMENT OF THIS ARTICLE BY THE COUNCIL, HOWEVER, IS NOT TO BE CONSTRUED AS HOLDING THAT THIS IS AN OFFICIAL PLAN OR ONE THAT MAY NOT BE MODIFIED TO MEET OTHER SITUATIONS.

PAUL NICHOLAS LEECH, Secretary

THE HOSPITAL FORMULARY

By ROBERT A. HATCHER and WENDELL J. STAINSBY, New York

Large hospitals find it necessary to limit the prescriptions of the staff mainly to selected formulas, and this system has tended to promote the use of proprietary formulas, which usually cost much more than their official equivalents without corresponding advantage. The physicians of the staff do not often come in contact with the purchasing department or with the pharmacy of the hospital but they are frequently interviewed by the representatives of pharmaceutical manufacturers, who persuade them that their preparations have marked advantages over the pharmacopeial.

The formulary of the New York Hospital was prepared by a committee, which invited representatives of every department to present formulas desired for their departments. In every case where a complex formula or a proprietary preparation was desired the advocate of it was requested to present evidence of its superiority over the equivalent official preparation, and unless such evidence was submitted the committee declined to admit the article, or, in a few cases, admitted it with the proviso that it would be deleted unless evidence was presented that would justify its retention in a subsequent edition of the formulary.

The committee adopted the following rules governing the admission of articles to the formulary:

Rule I. Simple official (Pharmacopeial) substances will be admitted (when requested) unless they have become superfluous.

Rule II. No article will be admitted (except for controlled research) before its therapeutic value has been established.

Rule III. No article of secret composition will be admitted.

Rule IV. No article which is sold under a proprietary name will be admitted under such a name if a substance of identical composition can be obtained under a nonproprietary name.

Rule V. No mixture of two or more active substances will be admitted unless evidence is submitted that the mixture presents therapeutic advantages over the simple substances.

Rule VI. No proprietary article will be accepted before it has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in New and Nonofficial Remedies.

Rule VII. Requests for articles not included in the formulary of the hospital, but which are desired for use in controlled research which has been approved by the head of the department in which the investigation is to be conducted, will receive consideration by the committee.

Rule VIII. It is the policy of the committee to discourage the intravenous and intramuscular injection of substances which should be administered orally.

A careful examination of these rules will convince one that no article which is essential to the treatment of the sick is excluded from the formulary. For example, insulin was admitted without question, because there is no pharmacopeial substitute. On the other hand, mere popularity was not accepted as evidence of value.

In a few cases members of the staff were so firmly convinced of the superiority of a proprietary preparation that a blind test was proposed. In one such case, each of several departments was supplied with capsules containing the official barbitol, and the therapeutic equivalent of a proprietary barbital derivative. These were labeled either A or B for the smaller dosage, and C or D for the larger with the statement that the capsules contained either barbitol or the derivative in question. This investigation has not yet been completed, but it is intended to analyze carefully the results of the reports of the several departments of the hospital, in order to determine whether the evidence supports the contention of the advocate of the proprietary article. If the evidence does show that it is superior to barbitol it will be admitted to the formulary. It is intended to pursue a similar policy in every case, so far as it is possible, so that no member of the staff can have any reason to feel that he is deprived of any drug which he considers essential, but he must furnish satisfactory evidence, in the form of reports of his own investigations or from the literature.

One member of the staff was so insistent on the superiority of a proprietary preparation of theobromine over the official preparations that one of us has conducted a pharmacologic study of the problem involving probably about 200 experiments. While the results of these experiments are not conclusive, they do not afford any evidence that the proprietary preparation has any advantage over the official Theobromine Sodium Salicylate. However, they do tend to throw light on the value of these preparations for the relief of cardiac pain in certain conditions.

As indicated in the rules, this does not interfere with the therapeutic study of any proprietary preparation, nor does it prevent the use by any department in the hospital of any substance concerning the superiority of which the staff is so firmly convinced that it is willing to conduct a scientific study of its uses, or to provide it at departmental expense. Since the publications of the formulary, the committee has continued to pass on the acceptability of various formulas and articles requested by the staff.

The committee could not have carried out its plans without the whole-hearted cooperation of the staff, and, with very few exceptions, the rulings of the committee have been accepted without protest after the whole subject had been discussed in considerable detail.

The use of the formulary has resulted in marked economy, but it is too early to determine the precise amount saved to the hospital. However, we are mainly interested in a system of rational therapeutics, and we believe that the use of official preparations is far more conducive to rational therapeutics than is the use of secret or semisecret preparations, or of a great variety of preparations having nearly similar effects and differing only in dosage.

This plan requires for its fullest success a highly skilled pharmaceutical staff capable of cooperating with the medical staff of the hospital in the conduct of therapeutic research. The training of men to fill the pharmaceutical positions in such progressive hospitals constitutes at once an opportunity, and a challenge to the schools of pharmacy, for there are few such pharmacists now available.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

VETAB

Manufacturer—Vitab Products Company, San Francisco
Description—Ground wheat germ and rice polishings
Manufacture—The ingredients are admixed in definite proportions and treated by heat in a rotating drum for destruction of insect infestation. The processed material is bolted on a silk screen separator, that which passes through is packed in cartons as Vetab. The maximum temperature to which the product is raised is 70 C.

Calories—3.9 per gram 97 per ounce.

Vitamin—Vitamin B assay: rat tests with Chase and Sherman method, 73 units per gram, 210 per ounce. (Wheat germ and whole wheat approximate respectively 283 and 43 units per ounce.)

Claims of Manufacturer—A rich source of vitamin B. Rich in the mineral elements calcium, magnesium, phosphorus, potassium and iron.

HORMEL FLAVOR SEALED VEGETABLE SOUP

Manufacturer—George A. Hormel & Co., Austin, Minn.
Description—Vegetable soup containing beef broth, tomatoes, potatoes, carrots, celery, navy beans, corn, rice, barley, string beans, lentils, peas, pimientos, okra, kidney beans, salt, and onion extract.
Manufacture—Dried navy beans, lentils, rice, barley and kidney beans are carefully inspected; foreign substances and imperfect grains are removed by special devices and by hand. The navy beans are ground before using; the other dry ingredients are used whole.
Fresh potatoes, carrots, celery and onions are cleaned by mechanical agitation in free running water and hand trimmed and cleaned with knives and water. They are inspected at least five times and are not exposed to the air for more than one hour after work of preparation has begun. Onions are peeled, chopped and placed in cheese-cloth bags to be cooked in

the broth. Carrots are mechanically peeled, freed from black spots and green tops by hand, mechanically diced, and again hand inspected. Potatoes are peeled by an electrical rotary water spraying machine, the eyes are removed, and the potatoes are diced and placed in cold water until used. Celery is devoided of root and leafy attachments, which are disposed of immediately. The stalks are dismembered, inspected, sorted, and placed in a rotary agitator, where they are freely sprayed with water, the water is drained off simultaneously with the spraying so as to assure removal of any insect spray residue. The celery is again cleaned by hand by skilled operators and inspected.

Purchased canned tomatoes, okra, string beans, peas, corn and pimientos are used. The tomatoes are heated in a steam jacketed kettle to over 77 C before using; discolored pieces are removed from the green okra, the string beans and peas are drained. If possible, vacuum packed corn is used; if not, drained regular canned corn is used. The juice of the pimientos is drained off; seeds and black specks of roasted skins are removed, and the pimientos are diced.

The beef broth is prepared from trimmings from U. S. Department of Agriculture inspected and passed beef. The fat is removed and ground separately. The ground meat in cheese-cloth bags and definite quantities of onions and ground fat are cooked in water containing tomato puree and salt. The bags are removed, the fat is skimmed off and the broth is strained through cheese-cloth.

Cans, on conveyor belts, are filled automatically with definite quantities of the respective vegetables; the beef broth is automatically added to fill the cans, which are sealed, cooked in retorts for ninety minutes at 100 C and twenty minutes at 115 C, and chilled.

Claims of Manufacturer—Nearly a pint of beef soup stock and fifteen vegetables in every can. Cooked in the can.

McCORMICK'S BEE BRAND IMPORTED PAPRIKA

Manufacturer—McCormick and Company, Inc., Baltimore.
Description—Ground dried paprika (pimenton, pimiento) (ripe fruit of *Capsicum annum* L.).
Manufacture—Spanish paprika is dried in the sun and ground after removal of the stems, seeds and placentas, producing a mild paprika. The powder is exported and packed in tins at the packing plant.

Analysis (submitted by manufacturer) —

SATURDAY, DECEMBER 2, 1933

ECONOMIC TRENDS AND THE WEIGHT OF CHILDREN

The continuance of the economic depression has given rise to many predictions as to its dire consequences to human health. Without doubt a prolonged period of unemployment and hardships incident to failing incomes is likely to affect seriously the standard of living in any country in which such situations arise. Economic collapse may naturally be expected to affect the food distribution of the population almost as readily as the failure of crops or the blockades of warring nations. The menace usually seems most threatening to the child population, for this represents groups of persons who, on the one hand, are least able to make adjustments on the spur of the occasion and, on the other, have peculiar needs represented by the demands of growth.

Malnutrition among children, always an interesting problem, has been emphasized recently through the publicity associated with the Child Health Recovery Conference called at Washington early in October by the Secretary of Labor. This conference was said to be called for the purpose of considering an emergency in child health due to the depression. Specifically, it was alleged that from six to seven million children in the United States are suffering from malnutrition due more or less directly to the economic crisis through which the country has been struggling for the past four years. The meeting disclosed certain fundamental differences of opinion. During the discussion of the recommendations of the executive committee of the conference, which called for an extensive program of physical examinations on a nationwide scale for the discovery of malnutrition, it became evident that many of those in attendance, including physicians with long experience in public health work, were by no means convinced that any increase in malnutrition had been demonstrated.¹ The statistics presented in support of the claim that millions of children are underweight as a result of the depression were challenged. The opinion

was advanced that a preventive program consisting merely of providing funds for supplying bread and milk in adequate amounts was all that would be necessary to guard against the possible development of undernourishment among children.¹

In the light of this conflict of opinions, special interest attaches to the study by Palmer² of growth in children in relation to the economic depression. This study was carried out in Hagerstown, Md, chosen because approximately twenty million of our people live in communities of similar character. In the composition of its population, employment, charitable agencies and other community characteristics, including financial, it is reasonably representative of others of like size. Palmer³ had already made studies of variability of weight among elementary school children in Hagerstown from 1921 to 1927. These studies were available to serve as a control for the current observations. Palmer concluded that the average weight of children in the two periods presents no consistent or statistically significant differences and that the variability of body weight, measured by the standard deviation, is not consistently different for the two periods as far as boys are concerned, but that the weight for girls is slightly more variable in 1933 than from 1921 to 1927. He found four fewer boys and forty-one more girls who were 12 per cent or more underweight in 1933 than would have been expected if the same proportions had been found underweight as in the earlier study. A further classification disclosed that among families of the unemployed, those of the partially employed and those of the regularly employed, the same differences existed as are commonly found between children of different socio-economic classes. Palmer concluded that there has been no obliteration or widening of the class differences during the period of the depression. A still further classification into groups receiving aid from charity and those not receiving aid shows that children in the former class are from 2½ to 9 pounds lighter than in the latter, and Palmer infers that children who are most in need of supplementary aid are probably receiving it.

It is acknowledged that weight alone is not a satisfactory criterion of nutrition, except in a general way, but may be used to a limited extent as a convenient general index. Comparative studies such as those of Palmer are more significant than the statistics derived from the routine weighing of thousands of children, often without supervision, by nurses and teachers. The situation in Hagerstown, as described by Palmer, is probably fairly representative. It does not justify hysteria about the increase of malnutrition as a result of the depression. That thousands of children are underweight may be conceded, unfortunately, that has always been so. That well considered measures ought

² Palmer C E. Growth and the Economic Depression. Pub Health Rep 48 1277 (Oct 20) 1933.

³ Palmer C E. Variations of Growth in Weight of Elementary School Children 1921 1928. Pub Health Rep 48 993 (Aug 18) 1933.

¹ Proceedings of Child Health Recovery Conference Washington D C Oct 6 1933. Children's Bureau U S Department of Labor.

to be taken for the correction of such a condition may also be conceded, as may the possibility pointed out by THE JOURNAL⁴ that the results of the economic catastrophes of the past four years may not be manifest at once. At the same time, care should be taken that measures advocated are sound and may reasonably be expected to accomplish the end sought.

The program advanced by the executive committee of the Child Health Recovery Conference leaves much to be desired, especially with respect to the proposal to examine, in what must be a hurried and superficial manner, millions of children. Fortunately the program was adopted as a recommendation only, and the state medical societies are to have a voice in its further development in the respective states. Emphasis on adequate food relief seems most sensible and immediately effective, utilizing the knowledge of health and nutritional conditions in the various communities, already possessed by physicians, by public health and relief officials and by social service organizations.

THE INTERNAL TEMPERATURE OF THE BODY

In the classic volume "Experiments and Observations on the Gastric Juice and the Physiology of Digestion," published by William Beaumont, America's pioneer physiologist, just a century ago, he records a series of observations made under various conditions on the temperature of the interior of the stomach of Alexis St. Martin. The records were secured by insertion of either a "mercurial" or a "spirit" thermometer through the gastric fistula. In the chapter of inferences that form the conclusion of Beaumont's book he stated "that the natural temperature of the stomach is 100 Fahrenheit, that the temperature is not elevated by the ingestion of food, that exercise elevates the temperature, and that sleep or rest, in a recumbent position, depresses it." Incidentally he pointed out that, when the distance of the inserted bulb from the pylorus varied, some variation in temperature could be observed amounting to three fourths of a degree, between the splenic and pyloric extremities." The accuracy of these records, like much of what Beaumont reported, receives a surprising confirmation in the data secured with thermometric apparatus of special construction a hundred years later. Hepburn, Eberhard Ricketts and Rieger¹ of Philadelphia have found that in 129 men the maximum gastric temperature was 101.8, the minimum 97.8 and the average 99.2. In 128 women the maximum was 102.2 the minimum 97.5 and the average 99.4. With each sex the gastric temperature was between 99 and 99.9 in approximately six tenths of the subjects, and between 98 and 100.9 in more than nine tenths of the persons examined.

The internal temperature of the body and its variations are not without considerable interest. Accurate determinations, in all but exceptional instances such as gastro-intestinal fistulas afford, have been few until modern times. In the Philadelphia observations, in a group of fifty-three persons the temperature of the upper part of the intestine lay between 98 and 100.1 F (average 99), and was within one degree of the gastric temperature. In a group of six persons the sigmoidal temperature lay between 100.8 and 101.5 F (average 101.2) and was higher than the oral temperature by two degrees or more.

Application of heat over the gastric and particularly the abdominal areas is often used to give relief when localized distress occurs there. It may be surprising to learn, therefore, that when physical therapeutic agents, such as the electric pad, hot water bag, infra-red lamp, diathermy, hot wet pack or ice bag, were applied locally none of the observed changes in visceral temperature exceeded the maximum variation in gastric temperature during similar periods of time in a control series. Hence the conclusion that the production of any reparative benefit by local application of heat or cold is conjectural. On the other hand, ingestion of either ice water (250 cc) or ice cream (90 Gm) produced a marked decrease in gastric temperature, followed by a rise, at first quite rapid, then progressively slower. The average recovery time was in excess of half an hour. Use of ice water in a test meal delayed the gastric emptying time by from fifteen to thirty minutes. Ingestion of hot drinks produced a marked increase in gastric temperature, followed by a decrease, at first rapid, then progressively slower. Hepburn and his co-workers obtained evidence that leakage of a cold beverage through the pylorus lowers the temperature of the upper part of the intestine by several degrees. This observation, they conclude, may throw light on the etiology of gastro-enteric disturbances in patients who have a rapid gastric emptying time and partake copiously of cold beverages.

Current Comment

THE ADMINISTRATION OF THYROXINE

There can no longer be doubt that thyroxine represents the effective iodine-containing hormone of the thyroid gland. As it has been prepared synthetically and the synthesized product has been subjected to conclusive therapeutic tests all debate about contaminating potent principles and other doubts as to the specificity of thyroxine itself can now be dispelled. A few milligrams of the substance introduced into the blood stream is sufficient to bring about a noteworthy augmentation of metabolism which may continue for some time. These facts of course, do not mean that thyroxine as such is identical with the product actually secreted by the thyroid but it does represent the functionally potent molecular group of the thyroid hormone. In

⁴ Deception, Death Rates, editorial, J. A. M. A. 99, 1354 (Oct. 16), 1932.

¹ Hepburn, I. S., Eberhard, H. M., Ricketts, Rowland and Rieger, C. L. W. Temperature of the Gastro-Intestinal Tract. The Effect of Hot and Cold Foods and of Physical Therapeutic Agents. Arch. Int. Med. 56, 131 (Oct.), 1932.

this respect it is in striking contrast to diiodotyrosine, an inert iodine-bearing amino acid that also has been isolated from the thyroid gland. One of the puzzling features of thyroxine from almost the outset of its discovery and isolation has been the repeated observation of the inefficacy or greatly lowered effectiveness of thyroxine when it is administered by mouth rather than intravenously. At first thought one would expect the purified hormone to be quite as potent as an equivalent amount of desiccated thyroid gland. Frankly there is a marked discrepancy in this respect. Observations at Rush Medical College in Chicago¹ afford at least a partial explanation in the relative insolubility of the pure hormone. Pure synthetic thyroxine had much less effect by mouth than its monosodium salt. According to Harrington and Salter,² the physical properties of thyroxine are such as to make it highly probable that the absorption of this substance after oral administration would be inefficient and erratic, the digestion product, on the other hand, possessing as it does a much wider range of solubility, might well be absorbed almost quantitatively. The Chicago clinicians point out that, in the digestion of desiccated thyroid, peptides and polypeptides of thyroxine are formed which have a wide range of solubility. They conclude that solubility of the thyroxine compound administered would therefore appear to be important and destruction by intestinal enzymes must be considered, but only future work will determine whether or not some other factor, as yet unknown, is also to be considered.

AMEBIC DYSENTERY

The attention of readers is called to a number of letters on amebic dysentery appearing in the correspondence columns of this issue of THE JOURNAL. There is widespread interest throughout the United States in the attempts to control the further spread of this disorder. Moreover, experience is bringing to light exceedingly important information relative to the proper treatment of the disease. Evidence is now available that cases are continuing to appear not only from the original focus of the disease but from secondary foci throughout the United States. As is pointed out by the investigators from the Johns Hopkins Hospital, the disease tends promptly to become a familial disorder once a single case appears in any family. Moreover, the long incubation period (from nine to ninety-five days) means that cases may continue to appear in the future not having been detected in earlier examinations. Thus, one case is reported in an individual who visited the hotel that was the original focus of the disease during the first week in October, after all sanitary precautions had been established, and the health department of the city of Chicago now reports that 10 per cent of the food handlers examined during November were found infested even after examinations of these food handlers had been negative in three previous studies. Experts in the investigation of amebic dysen-

tery writing from California reiterate the warnings that have been emanating from California and from the southern parts of the United States for the past ten years that sooner or later the spread of this disease will become a national problem.

FATTY INFILTRATION OF THE MYOCARDIUM

Sudden death associated with failure of the heart occurs now and then under conditions in which the easily identified causes seem to be lacking. When the characteristic anatomic changes responsible for interruption of cardiac function cannot be demonstrated, death may be ascribed to conjectured spasm of the coronary arteries, ventricular fibrillation, shock, or other functional disturbance. It has been recently stated¹ that, while undoubtedly fatal conditions are encountered for which a satisfactory explanation cannot be obtained by the use of present morphologic methods, it must be emphasized that such assumptions should be made only after careful study has ruled out the possibility of a morphologic explanation. An attempt to discover heretofore unrecognized or unaccepted fatal morphologic changes in the heart has been made, apparently with some success, by Saphir and Corrigan¹ at the Michael Reese Hospital in Chicago. They point out that fatty infiltration of the myocardium was a more conspicuous clinical and pathologic diagnosis a few decades ago than it is today. Modern clinicians mention this condition among cardiac disturbances but are cautious in their interpretation of its significance. Perhaps, they add, the fact that the clinical manifestations are so indefinite has relegated this disease entity to an obscure place in considerations of cardiopathy. According to the Chicago pathologists, however, there are occasional instances in which, in the complete absence of all other major lesions, fatty infiltration is the presumptive sole cause of death. The myocardium of the right ventricle is the region mainly affected. The infiltration leads to a replacement of the muscle fibers by fatty tissue. The muscle fibers primarily become atrophic and later apparently disappear. If the replacement by fat involves a large portion of the myocardium it may lead to sudden death, without any premonitory symptoms of heart failure. Saphir and Corrigan assume that, when such infiltration is present, factors which cause an increased demand on the heart and which under normal conditions could easily be compensated for may lead to sudden death. Fatty infiltration of the myocardium may be regarded as a morphologically demonstrable cause of heart failure and death in instances in which death clinically was thought to have been the result of functional disorders without a morphologic basis. Apparently, a myocardium that is the seat of fatty infiltration may carry on its function as well as a normal heart but has no reserve power. Perhaps, as Saphir and Corrigan further conclude, the use of modern methods of recording auscultatory phenomena may reveal some typical changes, likewise, if numerous electrocardiograms are

¹ Thompson W. O., Thompson P. R. and Dickie, L. T. N. Mono-sodium Thyroxine, Desiccated Thyroid and an Impure Sodium Salt of Thyroxine. *Arch. Int. Med.* 52: 576 (Oct.) 1933.

² Harrington C. R. and Salter W. T. The Isolation of 1 Thyroxine from the Thyroid Gland by the Action of Proteolytic Enzymes. *Biochem. J.* 24: 456 1930.

recorded it may be possible to link to fatty infiltration a low voltage or other unexplained electrocardiographic observations in patients giving no evidence of coronary sclerosis and myocardial fibrosis. They believe that a study employing all the modern diagnostic methods may reveal a definite symptom complex and establish a clinical picture that has as its pathologic basis fatty infiltration of the myocardium.

Association News

ANNUAL CONGRESS ON MEDICAL EDUCATION AND MEDICAL LICENSURE

Tentative Program

The Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association will be held in the Palmer House, Chicago, Feb. 12 and 13, 1934. The Federation of State Medical Boards of the United States and the American Conference on Hospital Service will participate in the congress. The preliminary program follows:

MONDAY, FEBRUARY 12, 10 A. M.

Review of the Accomplishments of the Council on Medical Education and Hospitals
Ray Lyman Wilbur, M.D., Chairman, Stanford University, Calif.
Philosophy of Professional Licensure
Justin Miller, J.D., Dean, Duke University School of Law, Durham, N.C.
Medical Education and Its Relationship to Society as a Whole
Robert G. Sprout, LL.D., President, University of California, Berkeley.
The Restoration of the General Practitioner
Dean Lewis, M.D., President, American Medical Association, Baltimore.

MONDAY, FEBRUARY 12, 2 P. M.

JOINT SESSION OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS AND THE AMERICAN CONFERENCE ON HOSPITAL SERVICE
Responsibility of the Hospital Trustee and the Relationship Between the Trustee and the Staff
Howard S. Cullman, A.B., President, Beekman Street Hospital, New York.
Symposium: Size and Scope of a University Clinic
Henry Houghton, M.D., Director, University of Chicago Clinics.
Nathaniel B. Van Etten, M.D., Vice-Speaker, House of Delegates, American Medical Association, New York.
John H. J. Upham, M.D., Dean, Ohio State University College of Medicine, Columbus.

TUESDAY, FEBRUARY 13, 9 A. M.

JOINT SESSION OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS AND THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES
The Principle of Reciprocity in Professional Licensure
Bernard C. Gavit, J.D., Professor, Indiana University School of Law, Bloomington.
A Study of the Administration of Medical Practice Acts
J. N. Baker, M.D., Secretary, Alabama Board of Medical Examiners, Montgomery.
Reciprocity Agreements
John R. Neal, M.D., Secretary, Professional Committee for Medicine, Illinois Department of Registration and Education, Springfield.
Medical Licensure in South America
William D. Cutter, M.D., Secretary, Council on Medical Education and Hospitals, American Medical Association, Chicago.

TUESDAY, FEBRUARY 13, 2 P. M.

The Incorporation of the Principles of Preventive Medicine in Clinical Teaching
Wilson C. Smillie, M.D., Professor of Public Health Administration, Harvard University, Boston.
The Teaching of Industrial Hygiene
Leverett D. Bristol, M.D., Health Director, American Telephone and Telegraph Company, New York.
The Function of the Physician in Public Health Education
W. W. Bauer, M.D., Director, Bureau of Health and Public Instruction, American Medical Association, Chicago.

TUESDAY, FEBRUARY 13, 2 P. M.

THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES
Tracking of Narcotics by Licensed Physicians
H. J. Anglin, United States Commissioner of Narcotics, Washington, D.C.
The Use of the Insurance Principle in Enforcing Medical Practice Acts
F. M. Brit, J.D., Attorney, Minnesota Board of Medical Examiners, St. Paul.

Business Session

The Annual Dinner of the Federation of State Medical Boards of the United States will be held at the Palmer House, Chicago, on Monday, February 12.

MEDICAL BROADCAST FOR THE WEEK

Talks over Network of the National Broadcasting Company

The American Medical Association broadcasts each Monday morning from 1:30 to 1:45, Eastern standard time (12:30, central standard time). The subject for Monday, December 4, is "Diet and Health." The speaker will be Dr. Morris Fishbein, editor of THE JOURNAL. Subjects and speakers for subsequent broadcasts will be announced weekly in THE JOURNAL.

Radio Talks from Station WBBM

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

December 5: The Food Law and Advertising
December 7: Fresh Air in the Home

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9:45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

December 9: Communicable Diseases Among Children

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSANS

Clinical Meeting—The Fort Smith Clinical Society conducted its ninth meeting in Fort Smith, November 7. Clinics were directed by Drs. Ira F. Jones and James H. Buckley, a symposium on goiter was presented by Drs. James W. Amis, Arthur I. Hoge and Frederick H. Krock, and a clinical pathologic symposium on cancer of the uterus, with Dr. Edward H. Skinner, Kansas City, Mo., speaking on "Radium and Radium Therapy." Other speakers included Drs. Herbert Moulton on "Visual Fields in Brain Lesion," Davis W. Goldstein, "Control of Leprosy in the United States," James A. Foltz, "Management of Fractures of the Long Bones," Miles E. Foster, "Essential Points in Skin Grafting," and Charles S. Holt, "The Acute Abdomen." Drs. Harold P. Kuhn and Ferdinand C. Helwig, Kansas City, Mo., exhibited specimens.

CALIFORNIA

University Drops School of Optometry—The School of Optometry of the University of Southern California, Los Angeles, went out of existence when the fall semester opened, according to the *Optical Journal and Review of Optometry*. There were several reasons for the university's dropping the school, the principal one, according to the report, was the lack of cooperation by the optometrists of southern California.

Symposium on Heart Disease—Conferences, clinics, discussions and demonstrations constituted the fourth annual graduate symposium on heart disease in San Francisco, November 22-23, under the auspices of the heart committee of the San Francisco County Medical Society, the San Francisco Tuberculosis Association and the health council of the San Francisco Community Chest. The program also included a symposium on arterial hypertension.

Pretzell Pleads Guilty—Paul Pretzell pleaded guilty in Los Angeles, August 2, to a charge of violation of the medical practice act and was sentenced to 180 days in the city jail. Pretzell claimed to be a doctor of medicine with a New York license *California and Western Medicine* reported. He was committed to jail in 1930 in Santa Ana County for a similar offense and served a term in the county jail at San Diego for vagrancy; it is reported. Claiming to be a registered pharmacist in New York, Pretzell also claimed that he attended medical school in Heidelberg, Germany, and at Columbia University, New York. He admits, however, that he never graduated and that he had never been licensed to practice medicine anywhere.

Imported Rags—An order was issued by Dr Jacob C Geiger, director of public health of San Francisco October 19, which calls for the more stringent enforcement of a local law, adopted in 1911, affecting the "wiping rag" industry. Accusations have been made and investigations have proved that some practices now employed are not in keeping with the local laws, which regulate the cleansing, sterilizing and sale and use of materials used for cleaning. To comply with the ordinance, this material must be boiled for forty minutes in a solution containing at least 5 per cent of caustic soda. Before being sold, each package of wiping rags must be plainly marked "sterilized wiping rags," with the number and date of the certificate given by the health officer of the city and county for the operation of the laundry where the material was cleansed and sterilized. Importers of wiping rags particularly of Asiatic source shall make advance written notification to the director of public health of each shipment of rags for the San Francisco market. All material shall be subject to inspection and examination by the health department and, on indication, shall be held in quarantine until the proper laboratory examination is completed.

COLORADO

Five Year Cancer Program—Cancer of the breast will be the theme of the five year program on cancer education soon to be inaugurated by the recently appointed committee on cancer education of the state medical society, according to *Colorado Medicine*. Four teams have been named to present symposiums on the diagnosis and treatment of cancer with emphasis on early diagnosis. Drs William W Haggart and Harry S Finney, Denver, and John B Hurtwell and George W Bancroft, Colorado Springs (surgeons). Drs Kenneth D A Allen, William W Wasson and Frederick E Diemer, all of Denver, and George A Unfug, Pueblo (radiologists), Drs Carl W Maynard and Josephine N Dunlop, Pueblo, and Wilfred S Dennis, William C Black, Jr, and Emerie I Dobos, all of Denver (pathologists).

CONNECTICUT

Two Cases of Psittacosis—Two cases of psittacosis have recently been reported in Connecticut, both of which were traced to parakeets shipped from California, according to the state department of health. October 29, one of two parakeets recently acquired by a family died after being "droopy" two or three days. The following day one member of the family became ill, and subsequent laboratory tests confirmed the diagnosis of psittacosis. Previously, a parakeet had died in Connecticut after it had been shipped from California to a retail store in New York and from there to Connecticut. At that time parakeets had been shipped to eight purchasers in Connecticut from the New York store. An investigation revealed that three had died, and, on recommendation of the health authorities, the others were destroyed.

DISTRICT OF COLUMBIA

Centenary Commemorating Unanue—The one hundredth anniversary of the death of Dr Hipolito Unanue (1755-1833), whose bust appears in the Hall of American Heroes in the Pan American Union, was commemorated at a meeting of the Washington Chapter of the Pan-American Medical Association, November 10. Speakers included Dr Manuel de Freyre y Santander, Peruvian ambassador, Dr Jose G Lewis, acting president of the chapter, Dr Prentiss Willson, president of the Medical Society of the District of Columbia, Dr George B Tribble, president of the International Medical Club, Dr Tomas M Caygas, president of the Clinical Club of Washington and Dr Aristides A Moll, secretary of the chapter. Unanue is credited with placing the teaching of medicine on a solid basis in Peru through the organization of an anatomic amphitheater in 1791 and of the San Fernando Medical College in 1812.

FLORIDA

Society News—The DeSoto-Hardee-Highlands County Medical Society was recently addressed in Sebring by Dr Walter A Weed, Lakeland, on diagnosis of lesions of the gastro-intestinal tract. At a meeting of the Duval County Medical Society in Jacksonville, October 3, the speakers were Drs George F Oetjen on first aid treatment, Harold D Van Schaick, head injuries, and Frederick J Waas, injuries to the abdomen.

Child Health Program—Recommendations of the Duval County Medical Society for the inauguration by the Jacksonville Health Department of a comprehensive child health pro-

gram were adopted, October 25, by the city commission, news papers report. According to the plan, the supervision of the health of children will begin at birth rather than just before entrance into school. Other features include the distribution by the health department, with each birth certificate issued, of schedules of minimum health requirements for infants and children, and the furnishing of blank health records for each child about to enter school, to be filled out by private physicians and returned to the department.

GEORGIA

Encephalitis Reportable—The board of health of Macon and Bibb County recently amended its regulation governing communicable disease to include encephalitis as a reportable disease. In the future, patients must be isolated and quarantined, while placards will be required on homes where the disease is present.

ILLINOIS

Program for Health Officers—The Illinois State Department of Health is holding a special program for health officers December 14-15, in Springfield. Drs Paul J Zentay and John W Eschenbrenner, Jr, St Louis will discuss epidemic encephalitis. Drs Arlington Ailes, LaSalle, Lloyd L Arnold, Julius H Hess and Lydia J Roberts, PhD, Chicago, diet and nutrition and Drs Jay Arthur Myers, Minneapolis, Robinson Bosworth, Rockford, Thurman B Rice, Indianapolis, and Gottfried Koehler, Springfield, school health problems. Dr James P Leake of the U S Public Health Service has been invited to participate in the symposium on epidemic encephalitis. The speakers at the banquet session December 14, will be Drs William A Evans and Allan J Hruby, Chicago, and Eben J Carey, Milwaukee. Participating in a round table discussion will be Drs Howard A Orvis, Winnetka, Wilmer M Talber, Decatur, John W H Pollard, Evanston, Elmer B Cooley, Danville and Harry O Collins, Quincy, all health officers.

Chicago

Dean Lillie Appointed Distinguished Service Professor—Frank R Lillie, PhD, dean since 1931 of the Division of Biological Sciences University of Chicago, has been appointed Andrew MacLeish Distinguished Service Professor in "recognition of his brilliant and fruitful service to the university." There are six endowed professorships for distinguished service in the university. Dr Lillie, a graduate of the University of Chicago received the degree of doctor of philosophy from his alma mater in 1894. He has been professor of zoology at the school since 1907 and chairman of the department since 1911. He has been associated with the Marine Biological Laboratory, Woods Hole, Mass since 1893 becoming president in 1925. He was managing editor of the *Biological Bulletin* from 1902 to 1926. Societies of which he has been president include the American Society of Zoologists, 1905-1908, and the American Society of Naturalists, 1915.

IOWA

Public Health Meeting—The Iowa Public Health Association conducted its eighth annual meeting, November 22, at Des Moines. The program included a round table discussion on "What Lay Organizations Can Contribute to a Statewide Health Program," under the direction of Dr Walter L Biering, President-Elect, American Medical Association and commissioner of public health of Iowa. Dr James P Leake, U S Public Health Service Washington D C, addressed a joint session of the association and the Physicians' Circuit Postgraduate Lecture Course on "The Recent Outbreak of Epidemic Encephalitis in St Louis." Other speakers included Drs Albert J Chesley, St Paul, Clarence H Kinnaman, Topeka, Kan, and Milford E Barnes, Iowa City.

LOUISIANA

Bureau of Credit Established—The Orleans Parish Medical Society has established a bureau of credit in New Orleans. Should a patient's name be placed on the delinquent roll, which is being compiled, and satisfactory arrangement for settlement of the account is not made within 125 days legal action will be taken in an effort to collect the fee, it was stated. Members of the society will be required to report monthly to the new department the names and addresses of all patients owing amounts for ninety days or more, if no arrangement has been made for the settlement. This information will be disseminated to all the physicians through monthly delinquent lists. The new plan will not interfere with the continuance of the charity work of the society.

MARYLAND

Dinner to Dr. Hawkins—The Allegany-Garrett County Medical Society feted Dr. Arthur H. Hawkins, Cumberland, with a dinner at its semiannual meeting, recently. Dr. Hawkins, who was president of the society in 1918, was presented with a silver service.

Home Care for Mental Patients—Emergency Measure—In an effort to limit admissions to state hospitals so that existing resources may be used to the fullest extent in the care of urgent and favorable cases, the state board of mental hygiene has asked physicians to urge private hospital care for those patients who can afford it, and home care for those patients to whom the public hospitals can offer only custodial care. The board requests that physicians commit only patients for whom the hospitals offer a chance of successful treatment, or those whose presence at home constitutes a menace. The board points out that, unless this plan is undertaken as an emergency measure over crowding and decreasing budgets will reduce hospital service to an almshouse level.

The "Healthmobile"—Seven counties in southern Maryland and on the eastern shore were visited by the "healthmobile" of the bureau of child hygiene of the state department of health on its tour this summer. During the eleven weeks of the tour eighty-five communities were visited and eighty-nine health conferences were held for the examination of infants and children under school age. Of 1,589 children examined 1,137 needed follow-up care of some sort, about 216 were underweight and 142 had unhealthy tonsils. Of the total number, 1,341 children were given dental examinations and 767 were treated by the dentist. Of the 614 children between the ages of 5 and 7 examined in preparation for their admission to school, 334 had not been vaccinated against smallpox. The parents were notified that the children would have to be vaccinated before they could be received at any public school in the state.

MICHIGAN

Auxiliary Entertains Society—The woman's auxiliary entertained the Wayne County Medical Society with a dinner November 14. The guest speaker was Prof. John Lewis Brumm, director department of journalism University of Michigan, on "The Menace of Efficiency."

Course in Electrocardiographic Diagnosis—The department of postgraduate medicine University of Michigan School of Medicine Ann Arbor gave a five and one-half day course in electrocardiographic diagnosis at the University Hospital November 6-11, under the direction of Dr. Frank N. Wilson, professor of internal medicine.

State Board Election—Dr. Theron G. Yeomans, St. Joseph, was elected president of the Michigan State Board of Medical Examiners October 13. Dr. Jacob D. Brook, Grandville, vice president, and Dr. J. Earl McIntire, Lansing, reelected secretary and executive officer. Dr. John J. Walch, Isernhima, was reappointed to membership on the board for four years.

Tuberculosis Survey—With a view to disclosing possible sources of infection a survey is being carried on in Kent County to determine the incidence of tuberculosis. Dr. Joseph D. Aronson is a representative of the Henry Phipps Institute of the University of Pennsylvania and of the Rockefeller Foundation is in charge of the work which is under the supervision of the state and county health departments.

Mayor Given Honorary Membership—The Wayne County Medical Society presented a certificate of honorary membership to John W. Smith, acting mayor of Detroit, October 30. The scientific program consisted of a clinical pathologic conference under the direction of Dr. Clarence I. Owen, assistant professor of pathology, Detroit College of Medicine and Surgery. Following the conference a reception was held in honor of Mr. Smith.

Physician Honored at Home Coming—Dr. Benjamin Clyde Yale was honored in a golden harvest jubilee celebration November 10 in recognition of the completion of fifty years in the practice of medicine. Mr. George Gough shared the anniversary with Dr. Clyde. A civic holiday was declared by the mayor. The event was in the nature of a home coming, commemorating the work of the pioneers and early settlers of the community where Dr. Clyde and Mr. Gough have lived for many years. More than 200 early residents acted as an honor guard for Dr. Clyde and Mr. Gough and books containing their signatures and tributes were presented to the two guests of honor. Speaker included Dr. Alpheus F. Jennings, Detroit and Mr. H. L. Pard of Lapeer. The principal speaker intro-

duced by Dr. Donald A. Pollock, was Dr. Udo J. Wile, professor of dermatology and syphilology University of Michigan Medical School Ann Arbor who reviewed the history of the class of 1883, of which Dr. Clyde was a member. Dr. William J. Mayo, Rochester, Minn., is one of the thirty-seven surviving members of the class of 117 students.

MISSOURI

Portraits Unveiled—Portraits of the late Dr. Joseph S. Lichtenberg, Kansas City, were unveiled at St. Joseph and Menorah hospitals, October 9. Dr. Lichtenberg had been a member of the staff of St. Joseph Hospital for thirty-six years and of Menorah Hospital since its founding.

Centennial Celebration of Beaumont's Experiments—The one hundredth anniversary of the publication of William Beaumont's "Experiments and Observations on the Gastric Juice and the Physiology of Digestion" was celebrated by the St. Louis Medical Society November 21, the one hundred and forty-eighth birthday of Dr. Beaumont. The program was as follows:

Dr. Major G. Seelig, Biographical Sketch of William Beaumont
Dr. Joseph Erlanger, William Beaumont's Experiments and Their Present Day Value
Dr. Robert E. Schlueter, Dr. Beaumont as a St. Louisian
Dr. Louis H. Behrens, Our Civic and Medical Debt to Beaumont

Photostatic copies of Dr. Beaumont's letters and documents, with other historical objects connected with his life and work, are on exhibition in the society's headquarters. Dr. Beaumont was president of the St. Louis Medical Society in 1840.

In Practice Fifty Years—A dinner was given by the Clay County Medical Society October 26 in honor of three members who had completed fifty years in the practice of medicine. Drs. Walter C. Hamilton and John W. Epler, Kearney, and John H. Rothwell, Liberty. Dr. Hamilton, who has practiced fifty-four years, was unable to attend. Dr. Clinton K. Smith, Kansas City, was the principal speaker, and invited guests included Dr. Spence Redman, Platte City, who has practiced in Platte County more than fifty years. October 11, Dr. Robert J. Morton, Clay Center, was feted at a banquet given by seventy-five physicians and dentists of the county, in recognition of his completion of a half century in medicine. Speakers on this occasion included Dr. John T. Axtell, Newton, Kan., and Dr. Jabez N. Jackson, Kansas City, who discussed cancer of the breast. Dr. Morton was formerly state senator.

Cancer Education Campaign—November 8 marked the opening of a cancer education campaign in Missouri, sponsored by the Missouri State Medical Association with the initial session presented in Nevada by Drs. Ernest Kip Robinson and Ferdinand C. Helwig, Kansas City. Dr. Joseph T. Hornback, Nevada, counselor of the sixteenth district, presided, and the program was in charge of Dr. Earl C. Padgett, Kansas City. The counselor districts of the state have been divided into five districts, and teams have been organized in various centers. Cancer of the breast will be the topic for discussion this year. Every session will include a public meeting for lay education, a diagnostic clinic for the benefit of the local medical profession, and a scientific program with the county medical societies. At the recent meeting of the state association in Kansas City the committee on cancer presented a recommendation urging that an educational campaign on cancer for both lay and professional groups be inaugurated in conjunction with the committee on postgraduate course and the state committee of the American Society for the Control of Cancer. The work is in charge of Drs. Padgett, Floyd H. Spencer, St. Joseph, John W. Williams, Jr., Springfield, Marcus Pinson Neal, Columbia and Elms Fischel, St. Louis.

NEW YORK

Hospital News—Memorial Hospital of Greene County, Catskill, was dedicated with formal ceremonies November 2. Drs. Lyle B. Honeyford, president of the Greene County Medical Society, George L. Branch, chairman of the hospital medical board and Thomas Parran, Jr., Albany, state health officer, made addresses. The hospital, which was opened for patients in August, has twenty-four beds and ten bassinets.

Society News—Dr. Richard S. Farr, Syracuse, was elected president of the New York Society of Industrial Medicine at the annual convention in Rochester November 2. Among the speakers was Dr. Frederic Jay Cotton, Boston, on "Treatment of Elbow Fractures." Dr. Thomas E. Walsh and Wardner D. Ayer, Syracuse, addressed the Onondaga County Medical Society November 7 on "spondylolisthesis and blood dyscrasias, respectively."

Association of Public Health Laboratories—At the autumn meeting of the New York State Association of Public Health Laboratories in Albany, November 3, Dr Rufus I. Cole, New York, was the guest speaker, on "The Outlook for Overcoming Pneumonia." Among other speakers were Dr Leroy U. Gardner, Saranac Lake, on "Laboratory Diagnosis of Silicosis"; Dr Ruth Gilbert and Marion Coleman, Albany, "Discovery of Carriers of Pathogenic Micro-Organisms Among Food Handlers," and Dr Richard J. Lebowich, Gloversville, who reported a case of measles encephalitis. Dr Ellis Kellert, Schenectady, is president.

New York City

Personal—Dr Max Lederer was the guest of honor at a dinner given by the department of pathology of the Jewish Hospital of Brooklyn, recently.—Dr Oswald Swinney Lowlesly addressed the Spanish Urological Society and the French Urological Association on "Surgery of the Kidneys" during a recent trip to Europe.—Dr William Hallock Park, director of laboratories, New York City Department of Health, was one of five alumni of the College of the City of New York who received the Townsend Harris Medal for achievement at the annual alumni dinner, November 18. This award was established two years ago by the class of 1906 and was conferred for the first time. Dr Park is a graduate of the class of 1886.

Anniversary of Anesthesia Society—The tenth anniversary of the American Society of Regional Anesthesia was observed at a special meeting at the New York Academy of Medicine, November 8, called the "George W. Crile Meeting." Dr Crile delivered a paper on "Anesthetics, Narcotics and the Sick Man"; Dr Edward M. Livingston, his official address as president of the society, on "Regional Anesthesia: Its Place in Medicine," and Dr Louis Gaston Labat, an address on "Clinical Manifestations of Sympathetic Disorders and Their Response to Nerve Blocking." Dr Carl Koller, who in 1884 introduced cocaine into surgical practice, according to the program of the meeting, was also a guest.

Society News—The Baltimore Medical Club of New York will hold its annual dinner at the Fraternity Clubs Building, December 7. The guest speaker will be Dr Charles Bagley, Jr., Baltimore, on the history of modern neurologic surgery. Dr Frank R. Oastler will show lantern slides of Yellowstone Park.—Drs William Bierman and Homer F. Swift addressed the Harlem Medical Association, November 1, on "Significance and Therapeutic Value of Hyperpyrexia" and "Rheumatic Fever," respectively.—Dr Jacob Arnold Barger, Rochester, Minn., addressed the Medical Association of the Greater City of New York, November 10, on "Differentiation of Varieties of Colitis According to Pathology and Management."—Dr Louis Hausman delivered the third afternoon lecture of the New York Academy of Medicine, November 17, on "Acute Infections of the Central Nervous System from the Standpoint of the Practitioner." Dr Charles R. Austrian, Baltimore, delivered the fourth, November 24, on "Differential Diagnosis of Pulmonary Disease with Special Reference to Tuberculosis."—A series of eight lectures on "Personality Education and Adjustment in Camp" is being offered to camp directors, parents, counselors and others who plan to engage in camp activities, by the Camp Directors Association of America and the Association for Personality Training. Dr Ira S. Wile delivered the first lecture, November 21, on "Personality and Mental Hygiene in Camp." They will continue through January 16.—Dr Charles H. Frazier, Philadelphia, addressed the Bronx County Medical Society, November 15, on "Brain Tumors: Diagnosis and Prognosis."—Dr Harry Koster delivered a Friday afternoon lecture before the Medical Society of the County of Queens, November 17, on "Diagnosis and Treatment of Peripheral Vascular Disturbances."—Drs Frederick Tilney and James P. Warbasse addressed the Medical Society of the County of Kings, November 21, on "Medical Problems in Delinquency" and "The Medical Library and Its Relation to Medical Culture," respectively.

NORTH CAROLINA

Society News—Drs Stephen W. Davis and Lester C. Todd addressed the Mecklenburg County Medical Society, Charlotte, October 17, on "Idiopathic Hypochromic Anemia" and "Food Allergy with Special Reference to Migraine," respectively. Dr Archibald A. Barron, Charlotte, addressed the society, October 3, on diagnosis of epidemic encephalitis, myelitis and meningitis.

New Officers of State Board of Health—Dr Carl V. Reynolds, Asheville, was elected president of the North Carolina State Board of Health November 13, and Dr Sylvester

D. Craig, Winston-Salem, vice president and chairman of the executive board. Dr James M. Parrott, Raleigh, remains secretary. Dr Hubert B. Haywood, Raleigh, and Mr. James P. Stowe, Charlotte druggist, are new members of the board recently appointed by the governor.

PENNSYLVANIA

Memorial Lecture—Dr Russell L. Haden, Cleveland, delivered the Emmerling Memorial Lecture under the auspices of the Pittsburgh Academy of Medicine, November 28. Dr Haden's subject was "Clinical Significance of Variation in the Erythrocyte of Man."

Society News—A symposium on diabetes mellitus was presented before the Washington County Medical Society, Washington, November 8, by Drs Cortlandt W. W. Elkan, Pittsburgh, John W. G. Hannon and Orville G. Lewis, Washington.—A public health meeting featuring Pennsylvania Health Day was held by the Allegheny County Medical Society, Pittsburgh, November 15. Dr Howard A. McCordock, St. Louis, related "The Story of the St. Louis Sleeping Sickness Epidemic" and Dr Logan Clendening, Kansas City, spoke on "The Heritage of Medicine." At the November scientific meeting of the society, November 21, papers were presented by Drs John M. Johnston, on "Failure of the Pulmonary Circulation," Joseph H. Barach and David H. Boyd, "Generalized Edema, Water Retention and Its Response to Intravenous Acacia," and Dr Samuel Glenn Major, "Tumor of the Mouth and Jaw."—Dr Thomas T. Sheppard, among others, addressed the Pittsburgh Academy of Medicine, November 14, on "Thyroid and Congestive Heart Failure."

Philadelphia

Personal—Dr Addinell Hewson, professor of anatomy and histology in Temple University Dental School, was guest of honor at an informal dinner given by the alumni association of the school, October 23.—Drs Herbert M. Goddard and John H. Frick were guests of honor at a dinner, October 30, given by the Physicians Square Club. Dr Goddard is president of the national organization and Dr Frick of the Philadelphia branch.—Dr William N. Parkinson, dean, Temple University School of Medicine, has been elected a member of the board of trustees of the university.

Society News—Drs John T. Farrell, Jr., Louis H. Clerf and John B. Flick will discuss diagnosis and treatment of bronchiectasis at the meeting of the Philadelphia County Medical Society, December 13.—Speakers before the Northern Medical Association of Philadelphia, November 20, were Drs Nathan Blumberg, on collapse therapy, Pascal Brooke Bland, intracranial hemorrhage in the new-born, and Fielding O. Lewis, tonsils in relation to systemic infection.—Dr Ross H. Thompson addressed the Philadelphia Neurological Society on "Encephalomyelitis Disseminata Following an Ascending Neuritis."

TENNESSEE

Personal—Dr Oscar S. Hawk, Kingsport, has been appointed medical director of Central State Hospital, Nashville.—Dr Eugene L. Bishop, state health commissioner, has been appointed director of health for the Tennessee Valley Authority, according to recent newspaper reports.

Society News—Dr Warren T. Vaughan, Richmond, Va., addressed the Sullivan-Johnson Counties Medical Society, Bristol, November 1, on allergy in general medicine.—Physicians in Fayette and Hardeman counties recently organized the Fayette-Hardeman Medical Society, with Dr George T. Brinkley, Fayette Corner, as president. Meetings will be held at the Western State Hospital, Bolivar.—Drs John L. McGehee and James R. Reinberger, Memphis, addressed the Gibson County Medical Society, Trenton, October 30, on tumors of the breast and toxemias of pregnancy, respectively.—Dr Thomas D. Moore, Memphis, was elected president of the Walnut Log Medical Society and Dr Charles Leroy Denton, Dyersburg, reelected secretary at the annual meeting at Reelfoot Lake, October 26. This society is made up of physicians of southwestern Kentucky and northwestern Tennessee.—The first of a series of meetings on child health care sponsored by the Tennessee State Medical Association and the American Academy of Pediatrics was held in Dyersburg, November 1, under the auspices of the Dyer, Lake and Crockett Counties Medical Society. Speakers were the following from Memphis: Drs William T. Pride, on "Prenatal Care and Its Effect on the Child"; Richmond McKinney, "Effect of Hypertrophied Adenoids and Diseased Tonsils on the Growing Child"; Edward C. Mitchell, "Care of the Well Child"; and Laurence J. McRae, DDS, "Importance of Child Dentistry."

VIRGINIA

Personal—Dr Ernest L Stebbins, Richmond of the staff of the state department of health, has been appointed director of the Henrico County health department succeeding Dr Allan L McLean, who recently resigned to become associate professor of preventive medicine at Dalhousie University Faculty of Medicine, Halifax, Nova Scotia

GENERAL

Wellcome Prize Awarded—The Wellcome Prize for 1933, consisting of \$500 and a gold medal, was awarded by the Association of Military Surgeons of the United States at its recent annual meeting in Chicago to Major Edgar Erskine Hume, librarian of the Army Medical Library Washington D C, for his essay on 'The Value of Studies in Health and Sanitation in War Planning'

Society News—At the annual Mississippi Valley Conference on Tuberculosis in Kansas City, October 5-7, Herbert M Cass, Huron S D was elected president, Dr Charles H Lerrigo, Topeka, Kan, vice president, and A W Jones, St Louis, secretary. Dr Arthur A Pleyte, Milwaukee, was chosen president of the Mississippi Valley Sanatorium Association, Dr William W Buckingham, Kansas City, vice president, and Dr David O N Lindberg, Decatur, Ill, secretary. The meeting in 1934 will be held in Cedar Rapids, Iowa

National Academy of Sciences—The autumn meeting of the National Academy of Sciences was held at Massachusetts Institute of Technology, Cambridge, November 20-22. Among medical subjects of papers were the following

Allan W Rowe, Ph D Boston Gaseous Metabolism of Some Dwarfs and Giants
Dr Roy G Hoskins Boston The Schizophrenic Psychosis with Special Reference to Homeostasis
Henry C Sherman Ph D and L A Ellis New York Necessary Versus Optimal Intake of Vitamin G (B)
Dr Simon Flexner New York The Nerve Path of Infection in Poliomyelitis and Its Significance
Dr John F Tulton Jr New Haven Conn Functions of the Premotor Area of the Cerebral Cortex
Walter R Miles Ph D New Haven Conn Ocular Rotation Centers for the Two Primary Axes

Prevalence of Communicable Disease—The number of cases of poliomyelitis reported to the U S Public Health Service for the four weeks ended October 7 for the country as a whole was 1,271, a decrease from 1,412 reported for the preceding four week period. These figures are higher than those for the corresponding period of 1932 but much less than those for the epidemic years 1931 and 1930, when 4,122 and 2,236 cases, respectively, were reported in the corresponding four weeks. Typhoid reached the lowest point for this period in recent years, with 3,093 cases reported, as compared with 3,553 in 1932. The incidence of scarlet fever for the period 8,107 cases was approximately the same as for the same period last year but was considerably in excess of the incidence for 1931, 1930 and 1929. The numbers of cases reported in those years were 6,428, 5,220 and 6,198 respectively. The prevalence of meningitis 130 cases was the lowest for this period in the five years for which data are available.—Newspapers have recently reported the closing of schools in Matherville Ill, because of an outbreak of whooping cough, in Vassalboro, Maine for infantile paralysis, and in Owensville Ind., for scarlet fever.—Two cases of smallpox, one of them fatal, in El Paso, Texas led the city health officials to vaccinate 100 nurses and employees in a general hospital to which one of the patients was taken before his illness was diagnosed and thirty five persons in the business concern where the other was employed.—More than 1,000 children in Dallas were immunized against diphtheria during the week ended November 4 in a fight against increasing incidence of the disease. Thirty-eight new cases were reported during that week as compared with twenty nine the previous week.

Deaths in Other Countries

Arthur W Meyer chief surgeon of the West End Hospital Charlottenburg Germany known for his operations for pulmonary embolism November 14 of a bullet wound self inflicted.—Ernest Edmund Maddox, London ophthalmologist known for his work in the correction of squint November 10 aged 73

CORRECTION

Chronic Ulcerative Colitis—In Dr Buic's closing discussion of the article by L A Buic and J A Bergen (THE JOURNAL, November 4 p 1466) the clause that reads 'From 1,200 patients 1,816 strains of the organism which we believe to be of etiologic significance should have read 816 strains'

The Reform of the Medical Curriculum

The agitation for the reform of the medical curriculum continues. The Edinburgh Students' Union held a meeting, which was addressed by Dr C M Wilson, dean of St Mary's Hospital Medical School. He said that there were two camps in the battle of the curriculum. The majority of teachers were convinced that a student must collect and store as many facts as possible. The minority, to which he belonged, believed that it was impossible to insure the public by merely stuffing students with facts, that, so far as any of us were safe, it was in proportion as our wits worked accurately in emergencies. The five years of the student's life should be devoted to developing his reasoning powers, to training and testing habits of thought, to educate him so that when he went out into the world he might be able to educate himself. The medical schools had become too concerned with the mechanical acquisition of facts. Surgeons complained that students, when they came from the dissecting room into the wards, shed their anatomy like a worn out garment. When they asked the anatomy professor whether his students would not remember their anatomy better if its clinical applications were pointed out, he replied that he was teaching anatomy as a pure science. But such shedding of anatomy pointed to sheer bad teaching. The student suffered from a glut of talking, which was not teaching. The evil of modern medicine was that it was too much removed from the bedside.

Dr Wilson also attacked the examination system. Dr Dickson, a member of the British Medical Association special committee on medical education, said that the curriculum should be directed to the turning out of the general practitioner, not of the specialist. His general education must be of a high order. He must acquire a sound knowledge of the elementary medical sciences, of which the teaching should be of an applied and coordinated character. He should be a specialist in minor injuries and minor surgery generally, familiar with common diseases, and have a thorough practical knowledge of midwifery. Far too much time was spent in the dissection of the dead body.

The following resolution was adopted unanimously. The present system of medical education is unsatisfactory. Important changes in the curriculum are essential, whereby more facilities for instruction in practical medicine should be available and more assistance given in the principles and practice of preventive medicine. The time for this can be obtained by modification of the teaching in the earlier scientific subjects, with some revision of the time devoted to the special departments of medicine and surgery.

The Osteopaths

The agitation for the recognition of osteopaths continues in the columns of the *Times*. Persons write the usual letters to the effect that after the medical profession failed to benefit them they were cured by osteopaths. The profession is accused of prejudice. But Lord Moynihan points out that no more importance can be attached to unorthodox medicine than to unorthodox chemistry or unorthodox physics. Medicine is at last based on foundations common to all science. He does not deny to the osteopath some competence in manipulative methods. The profession does not grudge him success, though it recognizes its infrequency and is not unfamiliar with its perilous accompaniments and its fatal disasters. Opposition rests on something more fundamental on his complete lack

of adequate training in the most elementary principles, which underlie all diagnosis, and in application of those principles in directing treatment. Such principles are based on a multitude of sciences—*anatomy, physiology, pathology and the like*—and on that trained clinical observation which seeks to determine not only the morbid local condition but also its correlation of the patient. Only by such inquiry can trustworthy diagnosis ever be made, and without it empirical treatment is haphazard. The expert application of a method, good perhaps in itself but unsuited to the local or general condition, can bring no advantage and may do irreparable harm. The practitioner who has failed to pass through a full curriculum is devoid of sufficient knowledge of disease or of the methods by which apparently similar maladies can be differentiated. This accounts for the frequent disasters of osteopathic treatment. Those who practice "unorthodox medicine" are not practicing "medicine" at all. They are as competent to do so as a student would be who spoke in terms of higher mathematics and did not know elementary arithmetic.

Dr Farquhar Buzzard, regius professor in the University of Oxford, in discussing the claim of the osteopaths for registration points out that the object of the Medical Register is to enable any one seeking medical aid to distinguish practitioners who have had sufficient training for the safety of their patients from those who have not. If there were a register of osteopaths or of chiropractors the layman would assume that his health was safe in their hands. Osteopathy is fighting a losing battle in America against rival cults, which have the advantage of novelty. Osteopathy is based on the theory that most, if not all, diseases are caused by the pressure of misplaced bones on nerves and vessels and can be cured by replacement. However attractive by reason of its simplicity this theory is contradictory to the principles of pathology as taught in every medical curriculum in the civilized world.

International Congress of Plastic Surgery

The annual period of congresses has begun. Since the close of the vacation period and before the opening of the universities, various special societies have held their congresses, some being of international scope. The halls at the Faculté de médecine, which are always at their disposal, are scarcely adequate for the many sessions. As some of the congresses are held simultaneously, a report cannot be given until after the publication of their proceedings. That is the case with the Congress of Surgery, which lasts a whole week.

The Congress of Reparative and Esthetic Plastic Surgery is a comparatively small congress, although its importance is increasing from year to year, which is peculiar since its field is rather restricted. This year the congress was international and many foreigners attended. The sessions lasted two days, under the chairmanship of Prof Jean Louis Faure and Dr Dartigues, its founder. Colonel Picot, president of the Association des mutilés de la face, victimes de la guerre, and member of the chamber of deputies sat on the platform, with a face frightfully slashed a living witness of the need of reparative and cosmetic surgery. Prof Jean Louis Faure in his presidential address, pointed out the shackles with which, all too often, the courts retard the development of plastic surgery when they impose crushing penalties on unfortunate operators on the pretext that cosmetic interventions are not resorted to for the sake of saving lives. Heavy fines are frequently imposed on operators when their clients do not obtain the results they anticipated. Cosmetic surgery, Professor Faure emphasized, has become more dangerous for the surgeons than for their clients.

Professor Manna of Rome spoke on the same subject and demanded that the limits of the responsibility of the surgeon in such matters be clearly defined. Dr Bourguet presented the results of his research on the plastic surgery of the nose and the ears. Dr Eckstein of Berlin spoke on the surgery of the face and the neck. Dr Claon of Paris, Dr Burnan of Prague and Dr Lluesma Uranga of Madrid presented different types of mammary surgery and repair of the breast, in which connection an excellent sound film of Dr Dartigues was projected. More than forty communications were read on widely different topics.

Meeting of French-Speaking Radiologists

The Congress of French-Speaking Electrotherapists and Radiologists was held for the first time, under the chairmanship of Dr Belot, who was assisted by Professor d'Arsonval, sometimes called the father of modern electrotherapy by reason of his discovery of the high frequency currents and the short waves. Among the foreigners present was Mr Coolidge, creator of the Coolidge tube. An important paper was presented by Ledoux-Lebard and Garcia Calderon on the technic of the radiologic exploration of the mucosa of the large intestine. Gilbert and Karnka of Geneva described the clinical results of the lesions revealed by this exploration. The second communication, offered by Professor Rechou of Bordeaux, was designed to explain the new applications of short and ultra short waves in therapeutics.

At the close of the congress special ceremonies were held at the Hôpital de la Pitié, during which Professor d'Arsonval bestowed a plaque on Dr Delherm, head of the department of electroradiology at the Hôpital de la Pitié, in honor of his twenty-five years of hospital service.

Congress of Gynecologists and Obstetricians

The Association des gynécologues et obstétriciens, presided over by Mr Henrotty of Antwerp met in Paris, October 7, under the chairmanship of Professor Couvelaire. In his presidential address the latter vehemently opposed the practice of subjecting certain persons to compulsory sterilization. It is a mystic idea to expect to improve the quality of a race by such absolutely arbitrary methods. Many men of genius have been the offspring of degenerates and neuropaths. While eugenics is a legitimate ideal, it should be based on different conceptions.

The first topic on the program was the surgical treatment of placenta praevia, on which Paucot of Lille and Reeb of Strasbourg presented papers. In a series of 1,724 cases, they found that the mortality of mothers, as a result of obstetric methods, amounted to 782 per cent. They emphasized that wide rupture of the membranes is responsible for only 240 per cent of the mortality in mothers and constitutes therefore a preferred form of treatment. The child mortality ranges around 51 per cent, although it is only 34.5 per cent in wide rupture of the membranes. The statistics for the surgical methods reveal the somewhat discouraging figure of 911 per cent of mortality among the mothers in a series of 477 interventions but the statistics extend over the last ten years and if one considers only the low cesarean operation the mortality is only 433 per cent. The low cesarean operation is thus shown to be the preferred method, so long as it is employed by surgeons only in from 10 to 30 per cent of the cases of hemorrhage. The child's chances have improved since the stillbirths have dropped to 2242 per cent. The speakers stated that hemorrhages due to low insertion of the placenta do not justify the systematic use of surgical methods, such methods are indicated chiefly because of wide rupture of the membranes. With this exception, one should resort to surgical methods. The low cesarean operation has been shown to be superior to any other treatment from the standpoint of the safety of the child. Hysterectomy is a procedure to which it is sometimes absolutely

necessary to resort to save the life of the mother. A long discussion followed. The two camps represented by the advocates of surgical intervention and the defenders of perforation of the membranes, with recourse in case of grave hemorrhage, to the transfusion of blood, held their ground. Professor Brindeau favors the conservative low cesarean operation in infected cases when transfusion has been ineffective. Professor Hauch of Copenhagen remains loyal to the Braxton Hicks maneuver and to the balloon dilator, although he admits that the fetal mortality is higher. He favored, however, more low cesarean operations. Metzger, Cathala Leroux (Nantes), Essen Moeller (Sweden), Masson (Bordeaux), Keller (Strasbourg), Cora (Turin), Delmas (Montpellier), Arricaza (Spain), de Snoo (Utrecht), Snoeck (Brussels), Labhardt (Basel) and Levy-Solal described in turn their preferences. The discussion led to no definite conclusion unless it is that the obstetrician should allow himself to be guided by the events.

The second topic on the program was pelvic tuberculosis, and four papers by Moulouguet, Brocq, P. Gibert (Lausanne) and Rochat (Lausanne) were presented. The blood origin of this form of tuberculosis is no longer questionable and its beginning in the tubes is equally certain. Under such conditions marriage is contraindicated. Tuberculosis of the cervix is the least frequent, that of the adnexa the most frequent (80 per cent). The diagnosis is difficult. Brocq reported good results in cases with ascites, from simple laparotomy followed by prolonged heliotherapy. Gibert recommended the use of ultraviolet rays in preparing the patient for operation and also following the laparotomy. Professor Daniel of Bucharest opened the discussion by citing 266 operative cases, 60 per cent of which presented simple genital lesions and 40 per cent peritoneal lesions. Mr. Muret (Lausanne) confirmed that the uterus is affected in 50 per cent of the cases. He advocated conservative surgery and highly endorsed heliotherapy. Mr. Villard (Lyons) is an advocate of surgical treatment but the operation must be adapted to the anatomic forms; must be conservative and must avoid the risks of intestinal perforation. J. L. Faure said that hysterectomy must be resorted to in the grave cases.

The last paper on "Treatment of Disorders Following the Artificial Menopause," upheld the hormone method of treatment and that of grafts. The disorders of the surgical menopause are essentially vasomotor or rheumatismal but sometimes of a nervous or psychic order. Organotherapy gives good results in the former cases but is less certain in the latter. It should be applied early, immediately after recovery from the operation on nine or ten days each month at a time corresponding to the date of the menses.

Fruit Juices in the Diet of Patients

Prof. Carl H. von Noorden, an authority on metabolism, has issued some interesting statements on the value of unfermented fruit juices in the diet of patients. In most fruits, unless enriched by the addition of sugar, the caloric content is too low to constitute the major portion of the total food requirement for an adult. In latitudes with a hotter climate that furnish products with a high sugar content (figs, dates, bananas, orange, grapes, sugar cane, melons, pineapples) these may supply often more than half of the food requirement. In Germany, the home-grown fruit on the average might cover from 10 to 12 per cent of the total food requirements of the German population while the imported fruits might contribute about 10 per cent more. In Germany, fruit plays the part of a highly valuable supplementary food. The enjoyment derived from eating fruit comes not only from the sugar content but also from the weak organic acid present in varying propor-

tions and from the abundance of savors. The mineral substances in the most common varieties of fresh fruits amount to only from 0.5 to 0.75 per cent of the weight. They are, however, of considerable value, because they occur in different proportions than in animal foods, vegetables and cereals. Of great significance for the diets of certain patients is the fact that most fruits have a low sodium chloride content. The vitamin content is important. In their abundance of vitamins, combined with a manifold composition, tomatoes offer a valuable addition to the diet. Tomatoes may be said to constitute a transition between a fruit and a vegetable. The expressed juice of most of the larger fruits is poor in vitamins since the latter are contained chiefly in the seeds and in the outer covering. Oranges and tomatoes, however, are an important exception since their expressed juices contain most of their vitamins. Since in most countries, except for the tropical regions, fresh fruits are gathered only at certain seasons and then usually in such large quantities that it is difficult to dispose of them before they deteriorate, it is a common practice to convert them into a more stable form. The conversion of the expressed juices of fruits into alcoholic beverages by a process of fermentation usually takes care of most of the surplus. For healthy persons, unfermented fruit juices are valuable as supplementary food by reason of the caloric content, which, if the sugar content is high, may equal that of the best whole milk, and with average sugar content will correspond to two-thirds that of whole milk. Another good effect of an abundant ingestion of fruit and of fruit juices is the prophylaxis against diarrheas. Von Noorden emphasized that there is no other food substance that so quickly, so emphatically and so immediately provides the muscles with energizing material as the types of sugar contained in fruit juices. Every other type of food including ordinary table sugar, requires previous transformation through digestive processes.

An extensive use of unfermented fruit juices is to be considered in selecting the diet for a patient for example in acute and chronic infectious diseases, in which, to be sure theoretically a selection of various food products is to be recommended but from the practical point of view a patient often gives evidence of loss of appetite which may prevent the application of a mixed diet. Well cooled fruit juices and sweet ciders or musts as a supplement to or in place of fresh or cooked fruits sit lightly on the stomach and increase the desire for other food. A patient confined to bed may often be given up to 1 liter of unfermented cider or must during the twenty-four hour period which will usually supply about one-fourth of the total food requirement. Another important effect which is produced by no other food that is admissible in grave disease conditions is the action on intestinal activity. If this effect is desired to a marked extent certain conditions easy to fulfill must be observed: the fruit juices, namely, must be taken early in the morning on an empty stomach. For this purpose from 0.25 to 0.3 liter is sufficient, the whole amount well cooled, being taken within a few minutes. Von Noorden called attention also to the good effects of fruit juices on renal activity, especially in feverish patients and in disturbances of the circulation. The effect is at least as great as (usually greater) and certainly more conservative than the action of numerous so-called diuretics of the older materia medica. This effect is often striking in feverish patients who are inclined to perspire; for example in tuberculous patients. If by means of fruit juices ample diuresis is produced and waste products are thus washed away, the weakening sweats often subside quickly to a great extent although not always since the cause of the condition varies considerably. Even more striking is the cessation of the trouble, some sweats occurring in obese patients as soon as it proves possible by means of fruits and fruit juices with exclusion of other foods to increase markedly the elimination of fluids and salts through the kidneys.

Births, Deaths, Marriages and Divorces in Prussia

Attention was called recently to the great decline in the birth rate and to some of the measures that the federal government has adopted to increase the number of marriages. In recently published figures for Prussia during the first quarter of 1933, a further marked decline in the birth rate is reported, there having been only 157,070 births, or 55 per cent fewer than for the corresponding quarter in 1932. On the other hand, there were 142,531 deaths, or 16 per cent more than for the corresponding quarter in 1932. The excess of births over deaths had dropped to 15 per thousand as against 44 per thousand in 1932. The number of marriages was 59,555, or 6 per cent fewer than in 1932. It may be added that the recent financial aid given to brides who fulfil certain conditions was not in operation at that time.

In Prussia in 1932 there were 314 divorces for each 10,000 marriages, as against 30 in 1931. Two thirds of the divorces were granted in large cities, Berlin having reported a rate of 85 per 10,000 marriages. In one half of the divorces, the husband was declared to be the guilty party, in one third of the cases both the parties to the marriage contract were declared guilty, and in only one sixth of the divorces was the wife found to be the guilty party. In considering these statements, account must be taken of the peculiar laws in force in Germany. This high divorce rate affects not only so-called inflation marriages (that is, belonging to the period immediately following the war) but 13 per cent of the divorces concern prewar marriages, many of which had been contracted more than thirty years previously. Only 8 per cent of the divorces in 1932 involved annulment of marriage contracts entered into during the war.

Changes Recommended in the Curriculum

The report of the committee for the reform of medical study headed by the dean of the Brno faculty of medicine, Prof Bohuslav Boucek, has been published. The report deals in its first part with fundamental problems in the present crisis in medical education. The main requirement for improvement in the present overcrowding of medical schools is a proper regulation of the admission of students. According to the report, the number of medical students admitted to the faculty of medicine should be reduced to the actual need for new practitioners in the country and to the actual teaching capacity of the respective faculties of medicine. Another radical change which the report recommends is the concentration of study in a given period of time on a certain subject, in contrast with the present system of teaching a diversity of topics to students simultaneously. The report sees a great advantage in this concentration not only to the medical student who will be able to devote himself fully to one subject after another but also to the teaching staff, as only a portion of the year would be allocated to teaching, the rest of the time being free for scientific work and research. The report expects that more individual instruction will result from the measures recommended. The examinations of the present day will be replaced by long time observation by the teaching staff, with the final examinations becoming a mere formality. The report anticipates financial difficulties in connection with this reform but maintains that a radical improvement in the education of medical students is not possible unless the numerical relation of the students to the teaching staff is radically altered. The medical curriculum proposed in the report would cover two years devoted to theoretical studies and three years to clinical studies. The teaching year is subdivided into three trimesters. Each one

of the trimesters would have twelve full weeks of work, with the last week devoted to examinations. The schedule of the day's work prescribes as a first lesson for every day an hour and a half of lecturing followed by an hour and a half of practice. The morning session is terminated by another lecture of an hour and a half by assistants in the respective medical subjects. The subordinate teaching staff is emphasized in the report in contrast to the present situation, in which most of the teaching is in the hands of the chiefs of the respective departments. The afternoon session follows the same schedule. Among the subjects recommended for the first two years of theoretical studies, a special curriculum on nursing is a novelty. According to the report it should be an introduction to hospital work in connection with the topics that are presented today under the heading "medical propedeutics." All examinations in the theoretical subjects should be over by the end of the second year, so that clinical work would start immediately with the beginning of the third year. This is a great advantage over the present method, whereby usually the first half of the third year is lost on examinations in theoretical subjects. The three clinical years are divided so that the mornings are devoted to hospital work and the afternoons to such theoretical subjects as pathologic anatomy, hygiene, experimental pathology and pharmacology. Social hygiene is introduced as an obligatory subject in the three clinical years. The report of this committee represents the most complete project for the reform of medical study that has been presented in Czechoslovakia. It should be an important step toward reform. The committee consisted of serious and honored members not only of the teaching staff of the faculty of medicine of Brno but also of representatives of medical organizations and prominent practitioners.

International Meeting of Otorhinolaryngologists

A session of the Collegium Otorhinolaryngologicum Amicitiae Sacrum was held in Prague in September, with Prof Antonin Preecehtel in the chair. This is an international association founded on the initiative of Dutch otorhinolaryngologists. The membership of each country is limited to ten persons carefully selected according to their scientific qualifications. The annual session held in various capitals is usually of a high scientific standard. The Prague session was attended by forty nine members representing fifteen different countries, including the United States. Germany did not send its representatives as was customary in preceding years. The main feature of the session was a report by Prof S J Crowe of Baltimore, who spoke on the Wever-Bray phenomenon on the basis of extensive experimental data. The experience gained at this session showed again that similar meetings in which the membership is limited to selected experts has more value for the advancement of knowledge than meetings with a large audience with varying standards of knowledge and experience.

A Region Not Affected by the Depression

A conference on a regional public health plan was held, October 15, in the city of Zlín, which is the seat of the largest shoe factory on the continent. The flourishing shoe industry has brought to this region powerful financial means, which are to be used to help develop the whole territory of eastern Moravia. This section of Czechoslovakia is hilly and has poor natural resources. The health standard of the population has always been low. Endemic goiter is present in the higher sections while in the valleys hyperthyreosis prevails. At this meeting a committee was organized to study the public health problems of the territory and to provide with the assistance of economists, geologists, architects and agriculturists a plan for the development of this territory. It appears that a great deal of the preliminary work has already been accomplished.

An encouraging part of the program is that the region has not been affected by the economic depression, because the local shoe industry was able to maintain employment on a high level. This experiment deserves the interest of the medical profession, because the initiative in the undertaking is in the hands of physicians and the whole plan will be formulated on the basis of public health requirements.

New Rules of Ethics

New ethical rules have been published for the chamber of physicians of the province of Bohemia. They prescribe loyal obedience to the chamber and an ethical attitude toward patients. A physician is allowed to practice in only one community. He may visit a patient in another place only in case he is called there, but he cannot maintain another office there. A physician's office sign shall contain only his name, his office hours, his degrees and the type of practice he is engaged in under the rules prescribed by the chamber. A physician is not allowed to place his sign on any other building than his own house. He is not allowed to place any other information on his stationery or other printed matter. The same applies to advertising, which is allowed only for three months after the opening of practice or for three weeks after any change of his practice. Advertising through the distribution of leaflets to the public is strictly forbidden. Physicians are allowed to circulate leaflets about their practice only to physicians of their territory when they start practice or if any change in its form takes place. Any other form of concealed advertising such as articles or visits, is prohibited. The splitting of fees and remunerations for referring patients is a serious offense against the rules. Medical fees must be kept within the limits prescribed by the chamber. Treatment without a personal physical examination of the patient is not allowed. A physician can apply for appointment only if there is a vacancy in a position. A physician must not undertake the treatment of a patient who is being treated by another physician. This does not apply to first aid. An exception is allowed also in case the patient visits the physician in his office. In case several physicians are called the one who arrives first takes over the treatment of the patient. Inspection visits prescribed by insurance societies must be made only in the presence of the attending physician. In case a medical practitioner is sick or absent, the physician who replaces him is obliged to defend most conscientiously the interests of his colleague. Every physician is obliged to assist another physician in case of necessity. A consultation with other physicians must be granted by the attending physician if the patient requests it. The consulting physician must safeguard conscientiously the interests of the attending physician. The consulting physician is not allowed to take over the patient on his own. No physician is allowed to criticize or qualify in any way the medical work done by another physician in the presence of a patient.

Death of Professor Slavik

Dr Vladimir Slavik for many years professor of legal medicine at the Czech faculty of medicine of Prague died at the age of 67 years. He obtained a medical degree in 1892 and immediately took up the study of legal medicine under the guidance of Professor Rumsberg, his great teacher and predecessor in the chair of legal medicine. After five years of research work he began lecturing on legal medicine and continued his work at the Institute of Legal Medicine of Prague until he became its chief in 1908. During his twenty-five years as head of this institution he built it up technically and scientifically. He was twice dean of the Czech faculty of medicine of Prague and in 1928-1929 served as rector of the entire university. Rumsberg can be considered the founder of the Czech school of legal physicians while Slavik was the one who translated

his theories into practical application. A treatise on sudden death as a problem of legal medicine opened his scientific career. Another large volume of his deals with the diagnosis of poisoning in the practice of legal medicine. His most popular work is a textbook on legal medicine, which became a standard reference book for medical students and lawyers. He was well known as a friend of students and for many years served as curator of the Mensa Academica in Prague. For a time he served also as a secretary of the Central Organization of Czech Physicians and as editor of the periodical *Casopis lékařů českých*.

RIO DE JANEIRO

(From Our Regular Correspondent)

Criteria for the Discharge of Lepers

Dr Nelson Souza Campos, in a communication to the Paulista Association of Medicine (*Ann paulist de med e cir* September 3) stated that the inspectors have conditionally discharged during July thirty-three leper patients as offering no more danger to the public health. It is the first time that this has happened in Brazil and the credit for it goes to São Paulo, which has the best and most complete organization to treat leprosy in this country.

The criteria for the discharge of a leprosy patient are as follows. The patient is carefully examined clinically, dermatologically and bacteriologically. He receives six months of treatment after which he is again examined. If found negative, he is classified 'under observation' and, during the subsequent six months, he is subjected to a monthly bacteriologic examination, after reactivation has been brought about with potassium iodide. If still negative he is transferred to a pavilion for 'closed forms' of leprosy, which is at present the Sanatorium of Padre Bento, where he is subjected to treatment for six months and monthly examinations. Consequently, this represents twelve negative examinations after reactivation and after being interned eighteen months. Clinically, his active lesions must have disappeared. He is then examined by a commission of specialists and may be discharged conditionally. During the next three years he has to submit himself every three months to clinical and bacteriologic examinations, after which he is discharged permanently. A positive examination or the appearance of any active lesion annuls all the prerogatives acquired and the patient is again considered 'under observation'.

A Medical Congress

The Paulista Association of Medicine has decided to promote, in November, a congress for the study of questions of medical-social interest. There will not be issued any special invitations and all physicians whether or not a member of the society, may participate if they decide to collaborate in any way in the scientific objectives of the congress. Individuals or societies should communicate with the secretary of the association for registration and payment of a special fee giving them the right to participate in the proceedings and to a copy of the proceedings. The subjects chosen for discussion are: 1 The Hospital Problem in the State of São Paulo 2 Inflammatory Processes of Biliary Ducts 3 Mega-Esophagus 4 Treatment of Syphilis in Infancy 5 Neurosurgery in São Paulo 6 Treatment of Gonorrhea 7 Value of Otorhinolaryngology in School Hygiene 8 Menstrual Disturbances 9 Laryngeal Tuberculosis in São Paulo 10 Collapse Therapy of Pulmonary Tuberculosis.

The Leukocytes and the Prognosis in Appendicitis

In a communication to the Brazilian Society of Internal Medicine on the leukocytic formula in appendicitis Dr Moreira da Fonseca presented two leukocytic indexes that aid in the

prognosis in acute appendicitis. The author called the first index the leukoneutrophil quotient and it represents the relation between the number of leukocytes and the percentage of polymorphonuclear neutrophils. Normally it averages in this country from 100 to 150, and when it drops to from 75 to 100 it is a sign of aggravation of the disease, when it is down to from 75 to 50 it indicates gangrene or perforation of the appendix. When this quotient is below 50 the patient probably will not recover. A leukoneutrophil quotient above 250 is a sign of suppuration if at the same time there is a leukocytosis. The second index, the karyoneutrophil quotient, represents the relation between the number of nuclei in 100 polymorphonuclears and the percentage of these leukocytes. It is based on the Arneith index and on the percentage of neutrophils. In this country the number of nuclei in 100 polymorphonuclear neutrophils is usually 300 and the percentage of neutrophils varies between 55 and 65. The normal karyoneutrophil quotient is from 4 to 5. The lower the quotient, the worse the appendicitis.

A New Leprosy Society

Through the initiative of the board of directors of the Sanatorium Padre Bento and with the assistance of the auxiliary inspector of prophylaxis of leprosy of the public health service, there was established in August a Paulist Society of Leprology to encourage the study of leprosy. Various subjects were discussed pertaining to the life of the new society.

Marriages

WADE SALEEM RIZK, A Surg, Lieut (j g) U S Navy to Miss Lois Durban Greiner of Kalispell, Mont. November 3

RALPH BERNARD MULLENB, Iowa City, to Miss Helen McCormick of New Auburn, Wis., in Chicago October 14

GEORGE WASHINGTON HOLMES, Winston-Salem, N C to Miss Lucille Stokes Field at Richmond, Va., September 9

JAMES NELSON DAWSON Lake Waccamaw, N C, to Miss Marjorie Robynette Goodwin of Wilmington, August 2

ALEXANDER STUART MOFFETT, Murfreesboro Tenn, to Miss Virginia Billings of Nashville November 1

LONNIE BONDURANT MOSELEY, Jackson, Miss, to Miss Frances Ransom of Aberdeen, September 5

JOHN M McDONALD, Attica N Y to Miss Hazel Kern Huffman of Niagara Falls, November 4

ALVIN LEROY MATHEIS Elmhurst, Ill, to Mrs Sue Ellen Lay Baisch of Oak Park, September 14

ALFORD GORDEY HENDRICK Atlanta, Ga, to Miss Pauline Brown in El Paso Texas, October 14

WILLIAM LOUIS PATMAN, Greensboro, N C, to Miss Nellie Fuller Gaskill at Greenville, October 31

LOUIS HENRY SWITERLITSCH Coraopolis, Pa to Miss Pauline E Reed of Fair Oaks, recently

JOHN KEILER MACK St Louis to Miss Grace M Smith at Webster Groves, Mo, September 2

HERMAN EDWIN MARTIN Sandy Hook Ky, to Miss Amelia Duley of Morehead in September

EMMETT AUGUST MEILI, Cochrane Wis, to Miss Cleo F Maher at Durand, September 18

EDWIN RUSSELL JACKA to Miss Kathryn Lenore Granms both of Pioneer, Ohio, recently

CHARLES H NICHOLS New York, to Miss Helen Davy of Nashotah Wis, November 1

WALTER LEWIS NALLS to Miss Aileen Lee Williams both of Richmond, Va. October 14

ARTHUR BURHAM JOHNSON to Miss Betty Gruenberg both of Toledo Ohio October 7

LINWOOD FARLEY, Courtland, Va, to Miss Evelyn Byrd Nelson, September 23

HARLEY E HENRY to Miss Ruth Conwell, both of Brownsville Pa, October 27

Deaths

George Lyman Richards ♂ West Dennis, Mass., Harvard University Medical School, Boston 1886, Chairman of the Section on Laryngology and Otology, American Medical Association, 1902-1903, and Delegate in 1904, member of the Rhode Island Medical Society, the American Laryngological Association, American Laryngological, Rhinological and Otological Society, American Otological Society and the New England Otological and Laryngological Society, fellow of the American College of Surgeons, member of the state board of registration in medicine, 1913-1916, at one time director of the American College for Girls in Smyrna, Turkey formerly on the staffs of the Union Hospital Fall River, Fall River (Mass.) City Hospital and the Cape Cod Hospital, Hyannis author of 'Nose and Throat Work for General Practitioner' on the editorial board of *Annals of Otology Rhinology and Laryngology*, aged 70 died, November 9, of cardiac decompensation and cerebral edema.

John Ferdinand Golden ♂ Chicago, Northwestern University Medical School, Chicago 1903, clinical professor of surgery, Loyola University School of Medicine fellow of the American College of Surgeons, clinical assistant in surgery, Rush Medical College, 1904-1906 instructor in surgery 1906-1910 and associate in surgery, 1910-1920 at his alma mater, on the staff of the Mercy Hospital aged 53, was killed, November 20, when he fell from an eighth story window.

William A Edwards, El Cajon Calif University of Pennsylvania School of Medicine, Philadelphia, 1881 an Affiliate Fellow of the American Medical Association, fellow of the American College of Surgeons formerly professor of pediatrics, University of California College of Medicine, Los Angeles, aged 73, died November 15.

Howard Rankin Weirick, Hibbing, Minn., Columbia University College of Physicians and Surgeons, New York 1896 formerly mayor, village president, health officer and member of the state board of health, on the staff of the Rood Hospital, aged 61 was accidentally shot and killed October 20, while examining a revolver.

Osee C Butler, Seminole Okla. University of Arkansas School of Medicine, Little Rock 1917, member of the Oklahoma State Medical Association past president of the Seminole County Medical Society, served during the World War, aged 47, died, October 27, in a hospital at Oklahoma City.

Edward Parish Lacey, Bessemer Ala., Vanderbilt University School of Medicine Nashville, Tenn, 1883, member of the Medical Association of the State of Alabama fellow of the American College of Surgeons, on the staff of the Bessemer General Hospital, aged 77, died, October 22, of uremia.

John Thompson McLean ♂ Captain, E O, U S Army, retired Long Beach, Calif Memphis (Tenn.) Hospital Medical College 1898 served during the World War aged 60, died, September 7 in the Veterans Administration Facility, San Fernando of pulmonary tuberculosis.

George Leedom Peirce, Elkins, W Va. University of Louisville (Ky.) School of Medicine 1894 member of the West Virginia State Medical Association served during the World War on the staff of the Elkins City Hospital, aged 61, died September 26 of diphtheria.

Whiting Sweeting Worden, Yokohama Japan, Syracuse (N Y) University College of Medicine 1886, formerly a medical missionary for many years physician to the American consulate at Yokohama and to the Japanese royal family, aged 74, died October 17.

John Francis O'Brien ♂ Boston Harvard University Medical School Boston 1892 member of the New England Otological and Laryngological Society, medical superintendent of the Sanatorium Division of the Boston City Hospital, aged 66 died October 27.

Harry Wynne Browning Little Rock Ark. University of Arkansas School of Medicine Little Rock 1911, member of the Arkansas Medical Society, aged 48 on the staff of St Vincent's Infirmary, where he died November 3 of heart disease and uremia.

Eugene Larkin Lawrence, Thorndale, Texas University of Nashville (Tenn.) Medical Department 1907 served during the World War formerly city health officer and member of the state board of health aged 56 died September 29.

Harold MacDonald, Schenectady N Y, Albany (N Y) Medical College 1910, member of the Medical Society of the

State of New York served during the World War, aged 48, died, November 2 of heart disease

Augustus William Foy, Denver, University of Michigan Medical School Ann Arbor, 1892 aged 74 died November 6, in the Denver General Hospital of injuries received when he was struck by an automobile

Frank Moseley, Williamson W Va University of Tennessee College of Medicine, Memphis, 1915 served during the World War, aged 48, died, October 4, in Hot Springs National Park Ark., of heart disease

Harris James Milliken, Bangor, Maine, Medical School of Maine, Portland, 1904 member of the Maine Medical Association, aged 55 died October 4, of chronic myocarditis and chronic interstitial nephritis

Alfred Guido Rudolph Castles, Los Angeles, Rush Medical College Chicago, 1871 aged 82 died August 8 in the Hollywood Hospital of cerebral embolus, abscess of the kidney and hypertrophied prostate

Henry Albert Wolff, Pasadena, Calif., College of Physicians and Surgeons, Medical Department of Columbia College New York 1877 aged 80, died, October 30, of carcinoma of the gallbladder and liver

Thomas Fillis Goodwin @ Mount Vernon, N Y, University of the City of New York Medical Department 1879 on the staff of the Mount Vernon Hospital aged 78, died, November 2 of angina pectoris

George C McClure, Ball Ground Ga., University of Georgia Medical Department, Augusta, 1901, aged 63, died, in October at a hospital in Canton, of an overdose of medicine, taken accidentally

Howell Venable Armistead, Newman Calif., University of California Medical Department San Francisco 1885, member of the California Medical Association aged 74, died September 12

Joseph Herman Castleman, Gladesville, Tenn., Vanderbilt University School of Medicine Nashville 1920, aged 42, died November 6, in the Martha Gaston Hospital Lebanon of pneumonia

Franklin Deo Sinclair @ Oswego N Y, Eclectic Medical College of the City of New York 1896, on the staff of the Oswego Hospital aged 62 died, October 29, of heart disease

Eldon E Lewis, Port Huron Mich., New York Homeopathic Medical College 1884 aged 73 died November 2 in a hospital at Detroit, of chronic myocarditis and arteriosclerosis

James Osborne De Courcy St Louis Hospital College of Medicine Louisville Ky., 1892 member of the Illinois State Medical Society aged 75, died October 26 of heart disease

Isaac J H Dunaway, Morehouse Mo Rush Medical College Chicago 1896 formerly secretary of the board of health of West Lebanon Ind aged 63, died October 16

John F McGarvey @ Lorain Ohio Jefferson Medical College of Philadelphia 1883 on the staff of St Joseph's Hospital aged 76 died November 6 of coronary thrombosis

Henry Curt Merten, Union City N J Medizinische Fakultät der Friedrich Wilhelms-Universität Berlin Prussia, 1887 aged 68, died suddenly October 21 of heart disease

Robert A Ferguson Bellair Ill Indiana Medical College Indianapolis 1878 member of the Illinois State Medical Society Civil War veteran aged 90 died October 21

William Herschel Knap Swarthmore Pa College of Physicians and Surgeons of Chicago 1886 aged 73, died, November 7 in Upper Darby of bronchiopneumonia

Fred Drew, Boston Harvard University Medical School Boston 1894 member of the Massachusetts Medical Society aged 67 died October 22 of cardiovascular disease

John Powell Hinckley, Fillmore Calif University of Vermont College of Medicine Burlington 1875 aged 79 died August 29 in Hueneme, of valvular heart disease

Mary A Hoehn Cincinnati Woman's Medical College of Cincinnati 1894 aged 78 died November 1 of cardiovascular and auricular fibrillation

John W Eckfeldt @ Brookline Pa University of Pennsylvania School of Medicine Philadelphia 1872 aged 82 died October 5 of chronic interstitial nephritis

John A Walker Helen W Va University of Louisville (Ky) School of Medicine 1892 aged 63 died September 21 in a hospital at Peckley of pneumonia

Frank Bartlett Miner, Seneca Falls N Y Long Island College Hospital Brooklyn 1892 aged 69 died October 29 in Glen Falls of cerebral hemorrhage

Paul Sanford, San Jose, Calif., Kentucky School of Medicine Louisville 1891, member of the California Medical Association aged 74, died, September 29

John Bird Easterly, Istrouma, La., Kentucky School of Medicine, Louisville, 1893, aged 65 died, October 21, in the Baton Rouge (La) General Hospital

James Robert Davis, Noble, Mo., Barnes Medical College, St Louis, 1905 member of the Missouri State Medical Association, aged 77, died September 7

James H Kennedy, Aberdeen, Md., College of Physicians and Surgeons, Baltimore, 1874, aged 85, died, October 26, of arteriosclerosis and acute prostatitis

Charles A Rife @ Kyger, Ohio, Starling Medical College, Columbus, 1882, aged 74 died, October 29, in the Holzer Hospital, Gallipolis, of carcinoma

William C Rebhan @ Springfield, Ore., Willamette University Medical Department, Salem, 1907, aged 49, died, September 19, of coronary occlusion

Anna Jeanette Erskine, Steubenville Ohio, Cleveland University of Medicine and Surgery, 1894, aged 74, died, October 31, of cerebral hemorrhage

Ralph Lee Alexander @ Ontario Calif University Medical College of Kansas City, Mo, 1903 aged 57, died, October 19, of a self-inflicted bullet wound

William W Hetzler, Germantown, Ohio, Medical College of Ohio, Cincinnati, 1884, aged 82, died, November 8, of cardiovascular renal disease

Thomas A Boothe, Cleveland, Texas (licensed Texas, under the Act of 1907), formerly postmaster of Cleveland, aged 76, died, October 12

Sidney Beall Clark, Long Beach, Calif., College of Physicians and Surgeons of Chicago, 1895, aged 63, died, August 25, of cerebral hemorrhage

William Henry Howitt, Toronto Ont, Canada McGill University Faculty of Medicine, Montreal, Que., 1870, aged 89 died October 20

Henry John Becker @ Sterling, Colo., St Louis College of Physicians and Surgeons, 1920, aged 44, died, September 26, of portal thrombosis

Addison Fordyce, San Diego, Calif., Columbia University College of Physicians and Surgeons, New York, 1924, aged 38, died August 25

Edwin A Steely, Anna, Ohio, Medical College of Ohio, Cincinnati 1873 also a druggist, aged 82, died, October 2, of enterocolitis

Oliver S Bell, Detroit Detroit College of Medicine, 1892, also a pharmacist, aged 64, died, November 7, of cardiovascular renal disease

Frank M Faries, Paris, Kv, Pulte Medical College, Cincinnati, 1885 health officer aged 72, died, November 4, of heart disease

Aloysius J McKinnon, Rio Vista Calif, University of California Medical School San Francisco 1903, aged 63, died, September 1

Louis Antonio Cribari, San Jose Calif College of Physicians and Surgeons, Los Angeles 1920 aged 41, died, August 18

George Perry Dunham, Mystic Conn Boston University School of Medicine, 1891 aged 69 died, July 5, of coronary thrombosis

William Washington Ashley, Newhall Calif, University of Missouri School of Medicine Columbia, 1875, aged 79, died, August 8

William Ernst Kramer, Milwaukee Rush Medical College, Chicago 1891 aged 69 died, October 27, of carcinoma of the rectum

Amos C Knestrick Wooster Ohio Long Island College Hospital, Brooklyn 1887 aged 82 died September 24, of senility

George H Cole Conneaut Ohio Cleveland Medical College 1892 aged 76 died suddenly November 2 of heart disease

Solon Philo Bradley Lansing Iowa Hospital College of Medicine Louisville Ky 1892 aged 68 died October 2

Simpson F Williams, Cordele Ga Physio-Medical Institute Cincinnati 1835 aged 81 died September 28

W Lowry Jeffers, Baileston Tenn (licensed in Tennessee in 1889) aged 73 died October 5 of senility

Carl Johnson @ Los Angeles Denver College of Medicine, 1891 aged 66 died September 14

Bureau of Investigation

THE NICHOLS SANATORIUM

Another Advertising Cancer Concern Using Escharotics

In Savannah, Mo., a small town a few miles north of St. Joseph, there has been for some years an institution known as the Dr. Nichols Sanatorium for Cancer. It was founded by one Perry Nichols. Perry Lewis Nichols held a diploma from the University of the South Medical Department, Sewanee, Tenn., 1901. He died in 1925.

THE JOURNAL has for years received inquiries from both physicians and laymen regarding the concern. To quote a few from the scores of inquiries received this year:

A woman in Kansas City, Mo., wrote:

I received a letter from friends in Michigan asking me to find out what I could about the Dr. Nichols Cancer Sanatorium in Savannah, Mo. I called the Jackson County Medical Society and they referred me to you. Is it a reputable hospital or just a quack concern?

A physician in Seattle wrote:

'Will you please give me some information on Dr. Nichols Cancer Sanatorium located in Savannah, Mo.?'

A physician in Indiana asked:

Please give me the status of the Nichols Sanatorium at Savannah, Mo.

From a town in Kansas came this inquiry:

One of my patients asked me concerning the status of the cancer hospital at Savannah, Mo. It has been my impression that this place does not rate very high.

A layman in Cincinnati wrote:

Enclosed is a letter I received from Dr. Nichols Sanatorium, Savannah, Mo. Have also received the book they refer to in their letter. Upon advice of my doctor I am writing you for information as to the credibility of this sanatorium.

A Canadian physician wrote:

I have today been advised by letter that my sister-in-law living in Vancouver has left for Dr. Nichols Sanatorium, Savannah, Mo., to undergo treatment for cancer of the breast. She has been advised to go there by well-meaning friends because surgery is not employed. Will you kindly advise me regarding this so-called cancer sanatorium?

The story of how Perry Nichols came to engage in the cancer-cure business when he was a young man was set forth at some length in a two-page newspaper advertisement that Nichols ran in a St. Joseph, Mo., paper in December, 1924. According to the story there given, Nichols in 1895 was selling real estate in Kingsley, Iowa, a short distance from Cherokee, Iowa, where there was an advertising cancer-cure outfit operating (presumably the Seaman Cherokee Sanitarium). A niece of Nichols was working at the Cherokee institution and Nichols, when visiting the niece, met the men who were running the cancer concern. They, for some reason not clear—unless it was that Nichols was what is known as a high pressure salesman whose capacity in this field could be used—invited him to become a partner in the Cherokee institution. He accepted the offer and, with the two men connected with the Cherokee Sanatorium, opened a similar outfit in Des Moines, Iowa. According to Nichols' story, they treated one patient—unsuccessfully—and then the partnership was dissolved. This was in June, 1896.

In November, 1896, Nichols started in the "cancer cure" business on his own responsibility, although he had no medical education. He treated patients who had, or thought they had, cancer, keeping within the law by engaging a licensed practitioner to assist him. Later Nichols obtained a medical diploma from a low-grade (Class C) institution that went out of existence in 1909. He first began practicing medicine at Watertown, S. D., with cancer-curing as a side-line. Within eighteen months he moved to Sioux Falls, S. D., and later to Hot Springs in the same state where he started his first cancer cure "sanatorium." He conducted this for some years in the meantime opening a branch sanatorium at Excelsior Springs, Mo. But Excelsior Springs would have none of him and passed an ordinance that resulted in Nichols' leaving that town. He continued to operate his Hot Springs institution until 1914 when he decided that he would get a little nearer the center of population and went to Savannah, Mo.

The Nichols concern, of course, uses the escharotic treatment. According to the statement that has been made for many years,

both before Nichols died and since, this has been vaguely described as:

"... a double compound about four times the strength of chloride of zinc plaster, or the arsenical or Marsden's paste and acts with decidedly less pain."

The claim is further made that the escharotic they use 'is not poisonous.' This contradicts the information furnished us by the Reverend Mr. W——, a Presbyterian minister who had also been a professor of biology. This gentleman's wife was induced to go to the Nichols Sanatorium. In a letter that Mr. W—— wrote to the American Medical Association, he thus described the situation:

"I was present at the Nichols Sanatorium the day Mrs. W—— was examined. A woman nurse who is now Superintendent of the institution since Dr. Nichols died examined my wife. The examination was concluded in less than ten minutes. The nurse felt of Mrs. W——'s breast (there was no sore), also felt under her arm, and said, 'The cancer extends under arm—serious case.' Mrs. W—— was assigned a room and the next morning was put under the influence of drugs while the arsenic poison was applied to burn out the supposed cancer."

"No effort was made at Dr. Nichols Sanatorium for Cancer to find out definitely if Mrs. W—— had cancer before administering treatment of arsenic poison in poultice form."

For nearly ten days Mrs. W—— was constantly under the influence of drugs. Then hurried out of Sanatorium three weeks from the day she entered to make room for other dupes and victims of this alleged 'Cancer Cure.'

Since Mrs. W—— left Nichols Sanatorium she has had a nurse and doctors—several nurses and several doctors. The arsenic poison has so filled her system and destroyed her vitality that she is now dying."

Nichols' institution seems to be conducted by a woman who was associated with Nichols for many years, as "Superintendent" and "Director of Treatments." In 1932 the Nichols concern listed as its "Medical Director" and "Plastic Surgeon" W. A. Stearns, M.D., with E. S. Metheny, M.D., as "Assistant."

In 1924 a year before Nichols died, prospectuses were sent out advertising 'First Mortgage Serial Coupon Gold Bonds' issued by the Dr. Nichols Sanatorium Corporation. These were to pay 7 per cent interest, payable semi-annually, and to mature in 1927, 1929 and 1931 respectively. The prospectus gave the amount of cash that Nichols had allegedly taken in annually from the time he started in 1905 up to and including 1923. In 1905 his cash receipts were \$3,300, in 1923 these had risen to \$201,600, with net profits amounting to \$71,720 after all expenses had been paid. The business has evidently been a profitable one.

The Nichols concern has for years issued elaborate and expensively prepared booklets, printed on deckle edged paper, with numerous illustrations both in color and monotone. A large part of the book lists according to states, the names and addresses of 'cured patients.' A few years ago the Bureau of Investigation, with the aid of the physicians of a county in Missouri, undertook to investigate all of the cases of patients whose names were given as coming from that county. Fifty-five cases were looked into. Investigation disclosed that forty-seven of the fifty-five patients were still living, eight were evidently actual cancer cases, for the patients were dead. Of the fifty-five patients, forty-three had had the diagnosis of cancer made, not by independent physicians, but by the Nichols concern itself! Three of the patients had their cases diagnosed as cancer by physicians, but no microscopic examination had been made, the diagnoses being of a clinical character only. In a few of the other cases detailed information could not be obtained.

In some of the older advertising one Jack Nichols was listed as being connected in some way with the Sanatorium. Although his picture has been published it is not at all clear just what place Jack Nichols has in the scheme of things at the Nichols Sanatorium. In July 1931, the American Medical Association received a letter reading as follows:

Gentlemen—As a member of the Dr. Nichols Sanatorium Incorporated and thru long association with this concern I have acquired a knowledge of what I believe constitutes a violation of the good practice of medicine.

If I can satisfy you as to the fact of this violation and will give you my full support, what may I expect from you by way of rectification in the same?

Sincerely yours

Jack Nichols

Mr Nichols' letter was answered as follows

We should say that it would not be necessary to have any long association with the concern mentioned in your letter to be convinced that there had been a violation of the good practice of medicine. We have been convinced of the same thing for very many years.

The Medicolegal Department of THE JOURNAL for October 7, this year, abstracted a legal case involving malpractice in which the Nichols Sanatorium was the defendant [*Gates v Dr Nichols' Sanatorium (Mo)*, 55 S W (2d) 424]. The plaintiff was one of the Nichols Sanatorium's victims, a woman who had gone to Savannah to be treated for two "lumps" in her right breast and one in the right axilla. A nurse diagnosed (1) her case as cancer and applied an escharotic mixture said to contain antimony and zinc chloride. As the escharotic began getting in its work, the nurse removed the necrotic tissue with surgical scissors and a curet. The entire right breast and a large part of the flesh in the axilla were thus removed before the victim left the Sanatorium. Fourteen months later she returned for treatment for another "lump" in the right axilla. The second course of treatment left her right arm useless. In the healing process the flesh united her arm to the side of her body. When she attempted to move her arm, the scars cracked and bled. She then went to a reputable physician, who performed a Wolf graft, which greatly improved her condition.

The woman sued the Nichols Sanatorium, alleging negligence and unskillfulness, and the jury returned a verdict in her favor. For some reason not clear, the judge overruled the jury's verdict and ordered a new trial, and the Kansas City court of appeals

affirmed the order of the trial court. The victim then appealed to the Supreme Court of Missouri. This, the highest court in the state in its opinion declared that there was ample testimony to support the allegations of the woman that the Nichols Sanatorium was negligent, that the Sanatorium had discharged the woman in a condition that rendered her practically an invalid for the remainder of her life, and it was a condition that could have been prevented or remedied. The Supreme Court also declared that the testimony showed that the Nichols concern used a method of treatment that has been condemned by the medical profession.

In the trial of the case in the lower court the Nichols concern undertook to introduce the testimony of one of its nurses to show that no more flesh was removed than was necessary to cure the diseased condition. The judge in the trial court ruled that while the Nichols Sanatorium might show what was done it could not introduce as evidence the opinion of the nurse, because, according to the judge that opinion was a mere conclusion and would invade the province of the jury. The Supreme Court much more rationally, took the position regarding this ruling that the nurse's testimony was properly excluded, not because it would invade the province of the jury, but because the nurse was not competent to testify. The judgment of the trial court awarding a new trial was reversed and instructions were issued to reinstate the verdict of the jury and enter judgment against the Nichols Sanatorium for the victim.

The various institutions of dubious scientific standing that advertise to cure cancer use in practically every instance, cauties or escharotics. Many persons especially those past middle age who develop benign growths assume that such growths are cancer and on their own responsibility go to these cancer-cure institutions that advertise that they do not use the knife. There the patient is told that the condition is cancerous, the growth is eaten out with cauties, the wound heals, and the patient goes back to his home a living advertisement for the cure of a cancer that never existed.

Correspondence

AMEBIC DYSENTERY

To the Editor—It is not without grim humor that California medical men join their colleagues of the Southern states in observing the dramatization by Chicago health authorities of an outbreak of amebiasis recently recognized in that city. The 1927 Chicago survey (Kaplan, Bertha, Williamson, C. D., and Geiger, J. C. Amebic Dysentery in Chicago, THE JOURNAL, March 26, 1927, p. 977) was of practical significance but the recommendations of this initial report obviously were not followed up. However, the present health authorities are to be congratulated on continuing this work and realizing its importance. Generally considered a "tropical disease," physicians in most of the United States have consistently refused to admit its potential menace as revealed by the extraordinarily high incidence of "carriers" without obvious symptoms (who have tissue damage, nevertheless) along with active cases found on systematic surveys of average populations in California and the South (Kofoid A. C. Twenty-Ninth Biennial Report, California State Bd of Health 1926, p. 93. 13.1 per cent in 6,834 persons; Kessel, J. F., and Mason, V. R., Protozoan Infection of the Human Bowel, THE JOURNAL, Jan. 4, 1930, p. 1. 9.8 per cent in 2,731 persons; Craig, C. F. The Amebiasis Problem, *ibid.*, May 7, 1932, p. 1615; Johnstone, H. G., David, N. A., and Reed, A. C. A Protozoal Survey of One Thousand Prisoners, *ibid.*, March 11, 1933, p. 728. 9.6 per cent in 1,000 persons). Current interest may focus public health attention on the problem with beneficial result, as implied by Dr. Bundesen and his associates (THE JOURNAL, November 18, pp. 1636 and 1638). Amebiasis, of course, should be reportable to health authorities.

The purpose of this communication, however, is to comment on the discussion of treatment of amebiasis as outlined in a review compiled from textbooks (THE JOURNAL, November 18, p. 1639). The review mentioned may give support to dangerous or inadequate therapy.

The only comprehensive disinterested critical survey of the treatment of amebiasis reported so far has been made cooperatively by the Pacific Institute of Tropical Medicine within the Hooper Foundation for Medical Research and the Pharmacological Laboratory of the University of California Medical School in San Francisco. The general results of this survey have been published in part (Leake, C. D. The Chemotherapy of Amebiasis, THE JOURNAL, Jan. 16, 1932, p. 195) and detailed special studies have also appeared. Referring to one of these (David, N. A., Johnstone, H. G., Reed, A. C., and Leake, C. D. The Treatment of Amebiasis with Iodochlorhydroxyquinoline [Vioform N. N. R.], THE JOURNAL, May 27, 1933, p. 1658), the review states "In their report they believe that Vioform is the most efficient drug of any type used in amebiasis." The only statement made by David et al. which could possibly be misinterpreted in such an unfortunate manner is the clearly phrased observation "In monkeys naturally infested with *Endamoeba histolytica*, iodochlorhydroxyquinoline was found to be more effective in nontoxic doses in completely and permanently clearing the stools than any mode of treatment yet reported on."

[NOTE.—This quotation is in error. THE JOURNAL quoted David, N. A., Reed, A. C., and Leake, C. D. The Treatment of Amebiasis with Iodochlorhydroxyquinoline, *J. Pharmacol. & Exper. Therap.* 48:271 (July) 1933.—ED.]

Most of the treatment discussion in the review is quoted from Dr. C. F. Craig (in *Musser's Practice of Medicine*, 1932, p. 241). The review states: "In the chronic cases Craig recommends continuous treatment with emetine bismuth iodide or chiniofon."

Continuous administration of any emetine preparation is very dangerous. Emetine and its derivatives may be lethal for mammals, including man, in a total dosage of from 10 to 25 mg per kilogram, regardless of the method of administration. Toxicity studies indicate that it is very slowly excreted or detoxified, so that cumulative poisoning may readily occur on repeated use (Anderson, H. H., and Leake, C. D. *Amer. J. Trop. Med.* 10:249 [July] 1930). Heart muscle bears the burden of the toxic effect of emetine, as shown experimentally and clinically (Rinehart, J. F., and Anderson, H. H. Effect of Emetine on Cardiac Muscle, *Arch. Path.* 11:546 [April] 1931). It is unfortunate that the review failed to point out the total amount of emetine that may be safely given without injury to the patient. In 1914 Vedder stated that a total of 10 grams (0.65 Gm.) should not be exceeded in the average human adult (*THE JOURNAL*, Feb. 14, 1914, p. 501). Later studies have confirmed this opinion with the recommendation that if emetine is used at all its dosage should be based on body weight and not exceed 1 mg per kilogram for a single dose or a total dosage of 10 mg per kilogram (Anderson and Leake).

Chiniofon (exploited under the trade names of "Anayodin" and "Yatren"), which is discussed in the review, is iodo-hydroxy-quinoline. In the only comparative study reported on this drug, it was shown to be the least effective in comparison with ten other related halogenated oxyquinolines. Of this clinical group of drugs, iodo-chloro-hydroxy-quinoline (vioform N. N. R.) was found to be best suited for clinical use. This drug, however, should not be employed rectally because of possible local irritation.

Two organic arsenical drugs are mentioned in the review, acetasone ("stovarsol") and carbarsone. The former is far more toxic in effective dosage than the latter, but this important information does not appear in the review. Toxic reactions with acetasone may be expected in about 15 per cent of patients treated at the dosage recommended, and many cases of poisoning with it have been published (Bender, W. L. *Am. J. M. Sc.* 174:819 [Dec.] 1927; Michael, J. C. Exfoliative Dermatitis from Acetasone, *THE JOURNAL*, Feb. 23, 1929, p. 645). Before the recent meeting of the American Society for Tropical Medicine, Anderson and Reed reported 330 cases of amebiasis treated with carbarsone, with 90 per cent success and only one mild untoward reaction in a patient with hepatitis. No other toxic effect from carbarsone has yet appeared. Chopra, Sen, and Sen of Calcutta (*Indian M. Gaz.* 68:315, 1933) have shown that carbarsone is definitely more effective in amebiasis than emetine, bismuth iodide or kurchi alkaloids. Presson (*Am. J. Trop. Med.*, to be published) has also confirmed the clinical value of carbarsone in agreement with Anderson (*Am. J. Trop. Med.* 12:459 [Nov.] 1932) and with David, Johnstone and Stanley (*Am. J. M. Sc.* 184:716 [Nov.] 1932), and also with the initial clinical report of Reed and his associates (*THE JOURNAL*, Jan. 16, 1932, p. 189). Carbarsone has an advantage in being susceptible of satisfactory rectal administration (Anderson, H. H., and Reed, A. C. *Am. J. Trop. Med.* to be published) in acute amebic dysentery. Carbarsone is certainly a highly effective drug in amebiasis, and because of its low toxicity on repeated dosage (Dr. J. C. P. Farrington of Lincoln, Neb., used a total dosage as high as 1,200 mg per kilogram over forty-eight weeks in thirty syphilitic patients with no sign of toxicity), and also because of its definite "tonic" action, it is clearly to be recommended in chronic amebiasis except when there is demonstrable liver injury. Here arsenic is contra-indicated. Emetine remains the drug of choice in amebic hepatitis or liver abscess.

Failure of recurrence of amebas in the stools of patients successfully treated with carbarsone or with vioform and maintained under proper controlled conditions eliminating danger of

reinfection has been demonstrated in a sixteen months follow up period by Reed and Johnstone (*Am. J. Trop. Med.* to be published). Danger from reinfection is thus shown to be a more serious concern for the physician than possibility of relapse after successful treatment. Unless the patient's environment is controlled, especially with regard to food handlers in his household, reinfection is a constant menace even in the face of adequate treatment.

The review does not mention the usefulness of bismuth subcarbonate in massive doses in controlling acute amebic dysentery, as emphasized by James and Deeks (*Am. J. Trop. Med.* 5:97 [March] 1925).

The review quite properly stresses Craig's criteria of cure as based on repeated stool examination. On the other hand, it unduly emphasizes the necessity of confinement to bed during treatment. While this may be indicated in patients weakened by emetine therapy, it is not necessary in the majority of cases when less toxic and more effective agents, such as carbarsone or vioform, are employed.

Empirical clinical observation has led to the use of many different types of drugs in amebiasis. The only systematic critical study of their relative values that has yet appeared has clearly indicated that (1) kurchi and ipecac (emetine) alkaloids are unsatisfactory since the former are too inactive and the latter too dangerous in doses necessary for effectiveness, (2) among many miscellaneous astringent and antiseptic agents bismuth subcarbonate is the only one proposed that deserves attention at present, (3) much more efficient halogenated oxyquinolines are available than chiniofon ("Yatren" or "Anayodin"), vioform being proved to be so on clinical trial, and (4) much less toxic and more effective organic arsenicals are available than acetasone ("stovarsol"), notably carbarsone, which on extensive independent clinical study has been found to give more satisfactory results with less untoward reaction than any amebicide now in use.

To the Editor—I wish to congratulate you on the excellence of the articles and the editorial on amebic dysentery that appeared in *THE JOURNAL*, November 18. Although it is regrettable that an epidemic of amebic dysentery should have started in connection with the Century of Progress Exposition, perhaps no better method of emphasizing the importance of this condition in the country as a whole could have been found. The wide publicity given to this epidemic will undoubtedly lead to the discovery of many cases of amebiasis throughout the country and a better understanding of the disease.

I think it is particularly important to emphasize, as a supplementary point in the diagnosis of amebiasis, that in addition to *Endamoeba histolytica*, man is known to harbor in his intestine at least four other amebas, none of which are pathogenic. It is just as important to be able to differentiate these amebas from *Endamoeba histolytica* as it is to be able to identify the pathogenic ameba itself. Whenever a supposedly unusual disease is called to the attention of the medical profession, many cases of other diseases are likely to be reported as the disease in question because of difficulties in diagnosis. The diagnosis of amebiasis should not be left to technicians who are not familiar with all the intestinal amebas. Authorities agree that it requires several months' training for a technician to become accurate in the identification of these parasites. One of the great needs at the present time is the better training of technicians along

this line. A good general rule for the ordinary laboratory in the identification of the motile form of *Endamoeba histolytica* is that no ameba should be so identified unless it is actively motile and contains red blood cells. In the identification of cysts there is also danger of interpreting cysts of *Endolimax nana* and four-nucleate cysts of *Endamoeba coli* as *Endamoeba histolytica*. In the presence of a simple diarrhea or following the administration of a cathartic, motile amebas of any of the five human species may be found in the stools, and caution should be urged in interpreting amebas discovered under such conditions as *Endamoeba histolytica*, even by the best of technicians unless active motility and the inclusion of red blood cells verify the diagnosis, or unless they can be checked by fixed smears stained with iron hematoxylin. In a disease such as amebiasis in which a permanent cure is difficult to obtain and in which specific treatment may prove toxic to the patient, accurate diagnosis is much to be desired.

HENRY E. MELENEY, M.D., Nashville, Tenn.

To the Editor—In THE JOURNAL November 18 attention was called to the present widespread dissemination of amebiasis. These reports will unquestionably stimulate a careful search for *Endamoeba histolytica* and where it is found, call for treatment. Emetine, no doubt, will be one of the drugs used. Attention is drawn to an article I published in the *American Journal of the Medical Sciences* (129:834 [June] 1930) in which I reported a case of fatal emetine poisoning due to cumulative action. The dose had been considered considerably less than the established minimal lethal dose. The conclusions I reached after a comprehensive survey of the literature were as follows:

1 There is no established method of administration of emetine that can be accepted with impunity. The drug being a proto-plasmic poison acts on the host as well as on the parasite.

2 Conclusions drawn from laboratory animals, owing to differences of species and of individual susceptibility, cannot be applied to man to determine the minimal lethal dose of emetine.

3 The minimal lethal dose of emetine may be passed without the advent of sufficiently severe symptoms of emetine poisoning, and death may occur from cumulative action after its administration has been discontinued.

4 Individual susceptibility to emetine cannot be recognized in advance, and each patient must be considered as possibly susceptible, to prevent the occasionally fatal case of emetine poisoning.

5 Emetine in very small doses, with frequent and sufficiently long rest periods, will be amebicidal. If the infection does not clear up on this basis the amebas are of an emetine resistant strain and other forms of treatment must be devised.

6 Present knowledge of the action of emetine on the human system is but poorly understood nor is its action on amebas definitely known.

7 There is no antidote for emetine poisoning.

FRANK J. IEBLY, M.D., Seattle

To the Editor—I have read with a great deal of interest the excellent reports of the epidemic of amebic dysentery in Chicago and the reviews of the general subject published recently (November 18) in THE JOURNAL. There is one point concerning the epidemiology and control of this disease which appears to have been overlooked or inadequately understood. Because of its importance from a practical standpoint I venture to bring it to your attention in the hope that you may see fit to give it the timely publicity it deserves.

The dysentery-producing ameba has a high multiple incidence in families or household. That fact was stressed by Kotoid

in 1923 (*Univ. California Chron.* 25:302 [July] 1923) and 1923 (*Proceedings of the International Conference on Health Problems in Tropical America*, 1924, p. 322), and more recently by Meleney in 1930 (*J. Parasitology* 16:146 [March] 1930). In my report (*Am. J. Hyg.*, to be published) of an amebic survey of the residents of a small mining community in Mexico it is pointed out that a considerable proportion of the cases of amebic infection occurred in households in which from two to four members were infected.

We have under observation at present in Baltimore a family that, in March, 1932, comprised a father, mother and eight children. Both parents and seven of the eight children carried *Endamoeba histolytica*, usually in association with four other species of intestinal protozoa. In another family composed of father, mother and two sons, we have found the dysentery-producing ameba in both parents and one of the boys. The probability is as Meleney has pointed out that the infected mother who in these families is the principal food handler, is the source of the infection for other members.

The implications of high multiple household amebic incidence as they relate to the epidemic extending from Chicago are (1) that not only public food handlers should be examined but the families of positive food handlers should also be examined and if found positive, treated; and (2) that in all cases of amebiasis, the other members of the household should be promptly examined and if found positive, treated. From the standpoint of prevention of this disease, little is accomplished by the successful eradication of the parasites in individuals, either for the affected persons or for the community if the danger of reinfection from other members of the family group is not guarded against. In my opinion many of the recurrences reported following apparently adequate amebicidal treatment are due to reinfections from intrafamilial sources rather than to relapses, as is commonly inferred.

Unless attempts at amebic control focus on the family rather than on the individual much of the effort that will undoubtedly be stimulated by the recent publications in THE JOURNAL will have been in vain.

JUSTIN ANDREWS

Assistant Professor, Department of Protozoology,
Johns Hopkins University

To the Editor—In view of the widespread epidemic of amebic dysentery that seems to be imminent may I take the liberty of offering some corrections of your suggested emetine regimen in the amebic dysentery review that appeared in THE JOURNAL, November 18. Nowadays since the reporting of quite a number of cases of severe emetine poisoning the combined employment of emetine hydrochloride by injection and emetine bismuth iodide by mouth is no longer considered safe for routine therapy. Instead emetine bismuth iodide is omitted and the hydrochloride is employed about as follows: one injection daily (1 gram for the adult, $\frac{1}{2}$ gram for children of eight to $\frac{1}{4}$ gram for younger children) for six days, and then one injection of just half these doses daily for the next six days. The adult will then have received 9 grams which is close to 10 grams (0.65 Gm.) which has come to be considered the safe amount to be administered in one course. During the rest period of ten days or more other drugs may be given, then the injections may be repeated or emetine bismuth iodide (which contains 20 per cent emetine) may be given in 1 gram dose (adult) three times daily for ten days.

The warning against intramuscular injection is perhaps unfortunate since subcutaneous injection of the hydrochloride is sometimes followed by pain, discoloration of the skin and even, though deep injection into the gluteal region is therefore considered the method of choice though it is painful also.

I may add that many physicians with abundant experience in the disease are now preferring to use Acetarstone, N N R (stovarsol), the adult dose of which is 4 grains three times daily, and emetine hydrochloride on alternate days for two weeks. One of our faculty members who was unfortunately infected in Chicago (the first one at least!) is now being satisfactorily treated in this way.

HARRY BECKMAN, M D, Milwaukee
Director, Department of Pharmacology, Marquette University School of Medicine

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

TREATMENT OF RINGWORM OF THE SCALP

To the Editor—Is there any known drug capable of penetrating the hair shaft in sufficient strength to destroy the fungus in ringworm of the hairy region and is croton oil a reliable method?

H H RITTENHOUSE M D, Bridgeville Pa

ANSWER—By the criterion given, tincture of iodine should be the best remedy, for it ranks high as a fungicide and penetrates the skin better than any other drug in this class, but this argument carries little weight, for the chief benefit from these drugs seems to be the inflammatory reaction caused by them, which results in immunity to the organism. The antiseptic action of the drug is useful chiefly in preventing the spread of the infection to others, and the depth of penetration is of value chiefly because of increased irritation. For this reason it is a fact, though it seems paradoxical, that deep ringworm infections like kerion of the scalp or beard are more easily cured than the common superficial microsporon infection of the scalp in children, which remains comparatively noninflammatory.

It is assumed that the question refers to ringworm of the scalp in a child. Some cases, particularly those in infants or very young children, can be cured by the persistent use of mild remedies, such as ointment of ammoniated mercury, from 5 to 10 per cent, applied once or twice a day for several weeks. In older children, sodium thiosulphate solution 14 per cent in water, can be rubbed vigorously into the affected areas twice a day until irritation results, when soothing applications, such as 10 per cent boric petrolatum, are to be applied until the irritation subsides, and then the same treatment is repeated. If a stronger method is desired, the same thiosulphate solution may be followed by a 3 per cent solution of tartaric acid, releasing sulphur and sulphurous acid. Strong measures are to be restricted to small areas of the scalp and not used for children less than 7 years old. Tincture of iodine may be painted repeatedly on an area an inch or less in diameter until a black crust forms. This should be torn off, to carry with it many diseased hairs. A soothing preparation is then to be applied until irritation subsides. Still more reaction can be obtained by alternating tincture of iodine and ointment of ammoniated mercury, causing an active dermatitis. Many other drugs and methods of this kind were in use before the epilating power of the X-rays was discovered.

Croton oil is the most severe chemical used for this purpose. It should not be used for young children, and if used should not be applied to an area more than half an inch in diameter. It may be introduced into the hair follicles with a hypodermic needle in the smallest possible amount. Within twenty-four hours pustulation results and the hairs can be removed. Soothing ointment should then be applied. This treatment causes follicular scarring and the hair does not grow again. It should therefore be used only when the bald spot can be concealed.

A milder method of using croton oil is its application in 10 per cent strength in olive oil, rubbing it into a small area and waiting for an inflammatory reaction. This may be strong enough to cure the infection without destroying the hair. If too little irritation results from a 10 per cent solution, it may be used in greater strength.

Mechanical epilation is highly recommended by authors of the pre-roentgen era but it is tedious and a difficult job. Only a small area can be epilated at one sitting and it is sometimes impossible to remove the diseased hairs because they break

easily. Shaving or chemical epilation were also used. Epilation by X-rays is a much more satisfactory prelude to treatment, but the treatment following it must never be irritating. It is limited to the application of mild antiseptics like tincture of iodine and is stopped when the skin begins to show too much drying.

With any method, frequent scrubbing with soap and water is indicated and the hair of the whole head should be kept clipped short to allow inspection and the detection of newly infected spots. This should be kept up for several months after apparent cure of any case of ringworm of the scalp. The English dermatologist Crocker said of the treatment of ringworm of the scalp: "I know of only one certain remedy, namely, persistence."

PARESTHESIAS

To the Editor—I have a patient about 40 years of age who complains of various paresthesias with a creeping sensation in the face and in the shoes, tickling sensation on top of the ear and burning in the tip of the tongue. He also has some numbness and tingling in the hands and feet slight dizziness at times and floating spots before the eyes. When he stands and looks at a still object such as a building, it appears to move slightly. He appears healthy and weighs 215 pounds (97.5 Kg.). The pupils are equal and react to light and in accommodation. The eyes rotate normally. The reflexes are normal except that the knee jerk is not pronounced. The Romberg sign is negative. There is no astereognosis. Sensation is intact for cotton, pain and heat. The blood pressure is 125 systolic, 80 diastolic. The urine is negative for albumin or sugar. The red blood cells number 6,160,000, with 90 per cent hemoglobin (he had come from a high altitude). There is no history of venereal disease but the Wassermann reaction is negative to alcoholic antigen and very slightly positive to cholesteralized antigen. The Kahn reaction is negative. What suggestion do you have as to diagnosis? Could the Wassermann reaction be disregarded? Two Wassermann tests were taken six months apart with an identical reaction. Kindly omit name and address.

M D, Iowa.

ANSWER—The only objective finding recorded in this case is the alteration in the blood count. This may, as suggested, be the result of a high altitude. In view of the paresthesias, however, for which no other explanation has been found, it would be wise to bear in mind the possibility of a blood forming disorder. The very slight reaction with a cholesteralized antigen can probably be disregarded. A psychiatric examination for the possible presence of a functional disorder is also indicated. No diagnosis is possible from the facts stated.

POSTOPERATIVE CARE IN TONSILLECTOMY

To the Editor—I should like to know the best preparations to use in the tonsillar fossae following a tonsillectomy to prevent hemorrhage and inflammation. What is the best preparation to use beforehand to prevent postoperative inflammation? Please omit name. M D, Indiana

ANSWER—Tonsillectomy is an unsatisfactory operation in a number of respects. Unlike the peritoneal cavity, wherein the surgeon makes every attempt to cover raw surfaces, tonsillectomy permits a large, raw wound to heal, in the presence of the normally infected secretions of the mouth and subjected to the trauma of swallowing. Hemorrhage that occurs at the time of operation or within a few hours should be considered primary. The best protection against hemorrhage of this nature on the assumption that the patient is suffering from no blood dyscrasia, is to use the principles followed elsewhere in surgery. Every bleeding vessel, vein or artery that does not spontaneously cease bleeding after a reasonable wait and following the use of sponge pressure should be seized and ligated. Oozing that is of no significance may be stopped completely by application of a mud made by soaking tannic acid in epinephrine, 1 to 1,000. Having the patient breathe through the mouth and small pieces of ice dissolved on the tongue, coupled with small doses of morphine for sedation, are also recommended as helpful in preventing bleeding shortly after operation.

A certain amount of reaction or inflammation follows every tonsillectomy. The best safeguard against reaction and hemorrhage, incidentally, is to do the operation with as little trauma as possible. As the healing of the raw surface takes place, first of all by the formation of a slough and then of granulation tissue and ultimate epithelization, from time to time so-called secondary bleeding may occur from approximately the fifth to the fourteenth day. Most of these hemorrhages can be stopped by sponge pressure or by the application of tannic acid in epinephrine, but occasionally one or more sutures are necessary to control the bleeding. There is no known way of preventing secondary hemorrhage, apart possibly from a careful choice of the time chosen for operation, and the physician should wait from ten days to two weeks following a sore throat before

attempting removal of the tonsils. Of course the patient's general condition should be as good as it is possible to make it and for four or five days following operation there should be no marked exertion. Gargles and local applications are of little avail in the hands of most men in reducing the painful and other distressing reactions following this operation.

ERYTHROL TETRANITRATE AND POTASSIUM THIOCYANATE IN HYPERTENSION

To the Editor—I should appreciate some information on the following: 1. Are there any harmful or undesirable effects from prolonged administration of erythrol tetranitrate drug in doses of 1 grain (0.065 Gm) three times daily in case of essential hypertension? 2. What is the value if any of potassium sulphocyanate in hypertension? What is its dosage and method of administration? Please omit name.

M D Massachusetts

ANSWER—1. If the dose is chosen too high, there is a dilatation of the blood vessels of the head with a feeling of heat and discomfort, even throbbing headache. The pulse becomes softer and more rapid. There may be general irritability. Often a dose of 0.03 Gm is tolerated without distress, when the larger dose produces disagreeable side effects.

2. Potassium thiocyanate, in doses of from 0.1 to 0.3 Gm three times daily, is capable of temporarily reducing blood pressure with improvement in symptoms in possibly one third to two thirds of cases. If the blood pressure reduction is excessive, untoward symptoms may occur, such as weakness, dizziness and drowsiness, which disappear when the drug is discontinued or its dosage is reduced. There seems to be a tendency to cumulative action, which may be prevented by taking blood pressure readings every week or two and possibly by omitting the medicine one day each week. It may be administered in syrupy solution, possibly the syrup of raspberry is as good a vehicle as any.

EFFECTS OF REMOVAL OF KIDNEY

To the Editor—Will you please tell me what effect the surgical removal of one kidney has on a person? Can he buy life insurance or what is the average life of a person after removal of one kidney? Thank you for any information you may be able to give me.

M M Thompson M D, Logan N M

ANSWER—Man can live even after all of one kidney and about half of the other have been removed or destroyed, provided the function of the remaining portion is not impaired. The removal of one kidney therefore should not of itself shorten life. The problem of expectancy of life after nephrectomy depends, of course, on the reasons for which the kidney was removed. If a tuberculous kidney has been removed but the patient's original tuberculous focus remains actively progressive, eventual involvement of the other kidney is, of course, a possibility. If the cause for which nephrectomy was done does not remain as a danger to life a patient can obtain life insurance, from companies which do not specialize in preferred risks, after a reasonable period of observation has passed to allow of studies to determine that function of the remaining kidney is adequate.

INDUSTRIAL HAZARDS ASSOCIATED WITH BIRCHWOOD

To the Editor—I have a request for information about a form of dermatitis that affects workers using birch in the wood working industry. Can you send a list of references on the subject? Since it is rather common among the wood workers in the factories of Maine it seems probable that articles and perhaps pamphlets have been written about this disease.

MARION COBB FULLER Maine State Library
Augusta, Maine.

ANSWER—No extensive body of published information on birchwood dermatitis is known to exist.

McCord (Industrial Hygiene for Engineers and Managers, New York, Harper & Brothers, 1931) states "In addition to mechanical irritation from the dust [birchwood saw dust], it is believed that this wood offers other opportunities for damage. The chemistry of birchwood reveals a rich content of complex carbohydrates. These polysaccharides are probably converted into simple sugars in the process of boiling birch logs. The presence of sugars on skin surfaces or in the eyes, favors bacterial growth."

In addition, it may be observed that workers with logs or in sawmills are prone to develop fungous infections of the skin and possibly of the lungs. If the logs are subjected to chemical treatment for the extraction of various tars, acids or alcohols these extracts are to be regarded as skin irritants in some instances.

VARIATIONS IN BLOOD PRESSURE

To the Editor—In Queries and Minor Notes (THE JOURNAL July 29), under the title of 'Variations in Blood Pressure of Arms and Legs', the statement is made that no real explanation is given except that the difference in pressure is due to differences in hydrostatic pressure. While this is undoubtedly true in part for the erect subject it cannot account for the definite difference of from 10 to 40 mm of mercury in a horizontal subject. Clinical blood pressure readings made with the usual arm cuff and manometer indicate only the air pressure in the cuff when the artery is collapsed. Any increase in thickness or resistance of the structures surrounding the artery will make a higher cuff pressure necessary before the artery can be collapsed. This may easily be demonstrated by taking blood pressure readings before and after wrapping several thick nesses of towel round the upper part of the subject's arm. Is not the greater tissue resistance of the leg the chief reason for the higher readings? If this idea is tenable it raises questions of much greater clinical importance which would well bear authoritative discussion. Does the obese patient with a high blood pressure reading really have high blood pressure or is the high reading due to increased tissue resistance? Is the blood pressure really raised in subjects with vascular sclerosis and calcification or does the hardened vessel wall merely require a greater cuff pressure to produce collapse?

RICHARD B. STOUT M D Elkhart Ind

ANSWER—Another explanation given for the elevated systolic pressure in the horizontal position in patients with aortic regurgitation is that the tonus of the arteries of the lower extremities is increased. This increase must be overcome before the blood enters the dependent parts and is in effect a compensatory mechanism. That such a hypertonus exists is shown by the fact that the application of heat to the leg will lead to a lowering of the systolic pressure. It has been shown that both obesity and the thickening of the blood vessel walls have a negligible effect on the actual blood pressure readings.

STERILITY

To the Editor—1. A man comes complaining of sterility. On examination of semen within fifteen minutes after ejaculation there is found an abundance of spermatozoa but there is no movement of them whatever. What is the probable cause of such an occurrence? What remedial measures would you suggest to overcome it? 2. A woman patient is anxious for conception. On examination of the husband spermatozoa are found in abundance and vigorously motile. Roentgen examination reveals the fact that both tubes in the female are patent. What would be your explanation for lack of conception and what would you suggest as an aid in this direction?

M D Montana

ANSWER—1. This may be caused by technical errors that kill the spermatozoa through overheating, chilling or exposure to some harmful chemical, by normal spermatozoa being exposed to toxic secretions from an inflamed prostate or seminal vesicles or by lack of vitality brought on by general constitutional disease, endocrine disturbances or local circulatory abnormalities such as are caused by varicocele. The treatment depends on the diagnosis and will suggest itself as soon as the diagnosis is thoroughly established, though in the nature of the case there are some conditions that are irremediable.

2. Further tests must be made to establish a diagnosis. Of these, the postcoital test is the most important. If it can be established that spermatozoa penetrate in large numbers into the fundus of the uterus and are able to live there, the diagnosis of failure of ovulation can be established. If not, there must be some abnormality of the cervical or uterine secretions, which should receive appropriate treatment. If there is failure of ovulation the basal metabolic rate should be determined and other evidences of endocrine disturbance searched for. There should also be a thorough physical examination to determine the presence of any organic disease. Finally, there seems to be with certain patients a functional sterility of psychogenic origin.

IODIDE IN CATARACT

To the Editor—What form of iodide is used in clearing progressive cataract and how should it be administered? Some publication appeared in a journal last year but I am unable to locate it.

P U Ducommun M D Camden Ark

ANSWER—No form of iodine will clear a progressive cataract. Sodium iodide has been used for many years as an eye wash in 2 per cent solution and internally following the dictum of Dor of Lyons but no real results have ever been proved. Weeks of New York advocated the local use of glycerin to arrest the progress of cataract but his conclusions have not yet been corroborated by others. Some five years ago a Committee was appointed by the Section on Ophthalmology of the American Medical Association to investigate the so-called medical cures of cataract. After extensive investigation, it reported no cures.

Book Notices

Combined Text Book of Obstetrics and Gynecology for Students and Medical Practitioners By J M Munro Kerr MD FRCP and S F C Oeg Regius Professor of Midwifery Glasgow University J Haig Ferguson MD LL D FRCS Consulting Gynecologist Royal Infirmary Edinburgh James Young DSO MD FRCS Gynecologist Royal Infirmary Edinburgh and James Hendry MBE MA BSc Professor of Obstetrics and Gynecology University of Glasgow With contributions from Charles McNeill MA MD Professor of Child Life and Health University of Edinburgh and J Duncan White MB ChB DMRE Radiologist Royal Infirmary Edinburgh Second edition Cloth Price \$10 00 Pp 110 with 509 illustrations Baltimore William Wood & Company 1933

This is the type of book needed in this country for medical students. It is not quite the size of the best textbooks on obstetrics (DeLee and Williams) and yet it contains almost all the information a student need obtain from a textbook concerning both obstetrics and gynecology. It is true that there exist systems of books which combine the two subjects and that more of these systems are in process of preparation, but these are obviously not suitable for most undergraduate students. It is needless to point out that in a combined textbook of obstetrics and gynecology there is omission of needless repetition. This book written by four of the leading teachers of obstetrics and gynecology of Scotland, is an excellent one beautifully written and abundantly illustrated. The four authors divide the responsibility for the entire book, because the reader has no way of identifying the author of any particular section. There are a few points in the book with which one may take exception. The authors maintain that spinal anesthesia is valuable in certain obstetric cases especially in

cesarean section. Most authorities, even those who are enthusiastic about spinal anesthesia, recognize that pregnant women are especially susceptible to the dangers of this form of anesthesia. No mention is made of direct infiltration anesthesia which is much simpler and far safer. Many of the illustrations show the vulva unshaved, especially for the delivery of a breech presentation. In the discussion on resuscitation of the new-born, there are illustrations of Schultze's swappings. This dangerous procedure should not even be mentioned in a textbook for students or practitioners. Likewise Byrd's method should also be condemned because far better and safer means of resuscitating new-born babies are available today. In cases of transverse position of the head the authors prefer to apply one blade over the baby's face and the other over the occiput rather than resort to an oblique application. The former method of applying the blades is surely more harmful to the child. The authors condemn rupture of the membranes as a means of inducing labor, because there is often a delay in the onset of labor and consequent risk of infection. This method of inducing labor is rapidly becoming popular in the United States and, when properly performed, entails but little danger. Laminaria tents are looked on as the safest method of inducing abortion by the authors, but a dilation and curettement is simpler and not more dangerous. The authors discuss accouchement force and illustrate the Bossi dilator for this purpose but this instrument was properly discarded long ago by most obstetricians. The authors advocate the use of an intra uterine douche for the removal of debris after an abortion and for the control of postpartum hemorrhages. Intra-uterine douches are entirely unnecessary after abortions and there exist much more satisfactory quicker and less dangerous methods of checking bleeding in the third stage of labor. The authors describe and illustrate the method of elevating a retroflexed uterus by means of inserting a sound into the uterine cavity and replacing the uterus. This is a hazardous and unnecessary procedure. In spite of these minor criticisms the book will prove to be of great value, for it contains most of the recent advances in obstetrics and gynecology.

Manuel pratique de dermatologie. Le diagnostic la peau et ses réactions thérapeutiques les dermatoses. Par A Desaux et A Bouteiller Avec la collaboration de Pierre Brocq chirurgien des hôpitaux de Paris. In two volumes. Cloth. Price 260 francs Pp 1232 with 640 illustrations Paris Masson & Cie 1932

Dedicated to the memory of Louis Brocq, a master of dermatology, this work follows his teachings but also contains necessary additions to bring it down to the present. The subject matter is divided into three major parts (1) diagnosis, (2) the skin and its reactions and therapeutics, and (3) the dermatoses. The authors propose that when confronted with a problem the student who has mastered the "dermatologic alphabet" or elementary lesions should consult the diagnostic part, where he will find the name and photograph of the dermatosis and reference to the section on 'the dermatoses' for more complete details. The illustrations, which are unusually good, bear descriptive legends, while further description and the differential diagnosis are contained in the text. In addition, many schematic drawings are reproduced to represent salient features. The illustrations are largely from the collection of Brocq supplemented by some from the museum of the Hospital St Louis and a few other sources. As one would expect there is a full description of the ingenious diagnostic method originated by Brocq and named by him 'grattage methodique'. Appended to the diagnostic part is an excellent discussion of the dermatology of the new-born. This explains the predisposition of new-born infants to certain dermatoses on the basis of structural differences between the infantile and the adult skin. The second section, which deals with the skin and its reactions is described in the preface as 'a series of working hypotheses founded on an accepted histophysiologic and biochemical basis through which the reader passes insensibly from the normal reaction to the inflammatory reactions of the integument, often prepared by modifications of the cutaneous soil'. This part of the work is also replete with illustrative schematic drawings and the remarkable clarity and systematization of the presentation stamps it as a masterpiece of dermatologic literature. The section devoted to dermatologic therapeutics includes a special article by Pierre Brocq on

surgery in dermatology Due regard is given to all accepted methods of treatment and the choice of selection of therapeutic agents according to the special character or localization of the lesion The third major division is on the dermatoses Here the teachings of Brocq are especially evident in such concepts as pruritis avec lichenification parakeratose psoriasiform, dermatites polymorphes douloureuses and dermatose figuree mediothoracique Particularly commendable are the sections on cutaneous mycoses and microbic dermatoses It is interesting to note the following dictum of Brocq, which is quoted in the dedication 'Bear in mind that to be a good dermatologist it is necessary to be a visualist, a patient and discerning analyst, a prudent clinician, a finished physician' The leading feature of this excellent treatise is the emphasis on clinical diagnosis, making it one of practical value The work of the publisher is entirely satisfactory

Le rôle biologique de la catalase dans le métabolisme d'énergie Par J. H. Regenbogen médecin à Leeuwarden (Hollande) 14 pages Price 36 francs Pp 139 Haarlem de Erven F. Bohn & A. Paris Gaston Doin & Cie 1932

In this monograph on catalase action the author reviews the earlier theories as to the action and function of catalase, also the more modern views on the liberation of energy in metabolism Each theory is discussed and its defects and values are presented The peroxidase and pH factors are treated separately in some detail, after which the author presents his own views and his own theory He points out that oxidative metabolism can be considered as a two phase process in which the anaerobic and aerobic phases proceed independently but rhythmically The rhythm is controlled in the main by the pH of the fluids at the surfaces of cells and by the effects of pH changes in the activation and inactivation of the enzymes involved in these processes The local pH changes the author considers to be automatically controlled by insulin through its control of fatty acid metabolism However, the pH factor alone is not sufficient for the complete control of the rhythm in the two phases Another factor enters and that is the formation and action of catalase The function of the catalase is to aid in making the separation of the two phases absolute and to protect the cell from self combustion in the aerobic phase through its destructive action of the hydrogen dioxide formed and bound by peroxides However, it does not destroy the minute traces of free hydrogen dioxide found in cells, which are so necessary for the destruction of cellular toxins and for the liberation of molecular oxygen for cell respiration The author emphasizes the need of an exact understanding of catalase action and function in connection with diabetes, arthritis, gout, obesity, arteriosclerosis malignant tumors, and many skin diseases

Physical Chemistry of Living Tissues and Life Processes as Studied by Artificial Imitation of Their Single Phases By R. Butner M.D. Ph.D., Professor of Pharmacology School of Medicine University of Louisville 140 pp Price \$5 1p 337 with 79 illustrations Baltimore Williams & Wilkins Company 1933

This is a systematic presentation of old and new observations on the physical and general physiologic aspects of the structure and activities of living forms The argument is that life is a scientific problem This argument is approached in three ways First much use is made of exceedingly simple models which in some degree simulate certain macroscopic features and behaviors of a few living forms The action of salts in the swelling of colloids in the transport of water and in osmotic changes is presented in simple language in connection with such models with the view of showing that similar mechanisms are at work in the living tissues In the second approach an attempt is made to study the microscopic structure of a number of Butschli's and Ieduc's models which show striking resemblance to certain living structures In this connection the author also presents his view that the crystallization of a pure substance involve internal structural and external surface forces that are similar to those involved in the growth of a cell or tissue The third approach involves a more detailed consideration of bio-electrical phenomena The author states that the production of bio-electricity primarily appears to be a characteristic of living matter just like color density viscosity and other physical qualities He considers the nature of the electric potential observed in living forms and emphasizes the impor-

tance of the heterogeneous composition of protoplasm and the differential action of solvents, solutes, phase boundaries and membranes in its control Naturally, the laws of electrical stimulation, the nature of polarization, the travel of waves of polarization and their physical causes are considered Other interesting material is given in later sections of the book, such as a brief treatment of artificial parthenogenesis and a fair review of Gurwitsch's observations on mitogenetic rays The appendix is devoted to a more mathematical treatment of investigations on membrane equilibrium and its bearing on water exchange swelling and osmotic pressure The author closes his arguments with a plea for the synthetic method of approach by means of artificial models, in spite of his admission that the difficulties involved in constructing one of the most elementary forms of life are practically insurmountable The work presents a good summary of the more obvious physical aspects of general physiology, with possibly a tendency to make the problem seem less simple than it really is from a purely chemical point of view One is struck by the tendency to ignore the importance of specific tissue constituents and of specific tissue activities in the normal physiologic history of a cell or tissue

Urographic Urology By Stanley R. Woodruff M.D. F.A.C.S. Associate Professor of Urology Columbia University and New York Post Graduate Medical School and Hospital Cloth Price \$15 Pp 235 with illustrations New York Wainlich Printing Company Inc 1931

This presentation is essentially clinical No attempt is made to go into the details of histology and pathology When laboratory details are of interest they are mentioned The subject matter is excellently arranged The illustrations are unusually clear and sharply defined and the various lesions are generously illustrated The monograph serves as an excellent everyday working aid not only to the urologist but also to the roentgenologist to the surgeon and to the internist, who so often are confronted with borderline problems in differential diagnosis The author is to be complimented particularly on his discussion of each case under the heading of urologic impressions The appearance of the urograms and the clinical history together make for simplicity in reference by the busy practitioner

The Diagnosis and Treatment of Diabetes and the Use of High Carbohydrate Diets By W. Wilson Ingram M.C. M.D. Honorary Physician and Physellan in Charge of the Clinic for Diabetes Mellitus Royal North Shore Hospital Sydney and G. V. Rudd M.Sc. Research Biochemist Institute of Medical Research Royal North Shore Hospital Sydney With preface by C. G. Lambie M.C. M.D. FRCP Boschi Professor of Medicine University of Sydney Cloth Pp 88 with illustrations Sydney Australia Angus & Robertson Ltd 1933

This gives the shortest and simplest possible exposition of the diagnosis and treatment of diabetes mellitus Although it is intended primarily for the physician the almost complete absence of technical terms and the elementary nature of the theoretical references make the volume suitable for the well informed layman The book is particularly designed to meet the conditions of medical practice in Australia, and the dietary instructions are based on the energy requirements and food materials indigenous to that continent The diets advised by the authors are presented in a series of weighed daily diets of ascending caloric value in which the food materials may be varied by the use of substitution tables All diets are moderately high in carbohydrate, the fatty acid dextrose ratio being 0.75:1 throughout As in all similar dietary systems flexibility for individual requirements is sacrificed to simplicity

A Laboratory Manual of Neuro Anatomy By C. L. Davis M.D. Professor of Anatomy University of Maryland and H. S. Rubinstein B.S. M.D. Instructor in Neuro Anatomy and Assistant in Medicine University of Maryland Part II Stereographic Plates Boards Price \$3 30 plates Baltimore William Wood & Company 1933

It is difficult to review the second part of a work of which the first part has not yet been published The material at hand consists of a series of thirty stereoscopic photographs illustrating the gross structure of the brain They are well chosen and accompanied by excellent descriptive sketches They will be useful to students and teachers of psychology who have need of rudimentary information concerning the structure of the brain but cannot supplant an actual dissection as an introduction to the study of the brain in medical schools

Miscellany

MATERNAL MORTALITY

Abstract of the Report on "Maternal Mortality in New York City," 1930, 1931, 1932, Issued by the Committee on Maternal Mortality of the New York Academy of Medicine

In 1930 the New York Academy of Medicine organized a committee of physicians to study maternal mortality in New York City. The work of the committee was conducted with the aid of a grant from the Commonwealth Fund.

In the three years embraced by the study, 2,041 maternal deaths occurred in New York City. Of this number the committee estimates that 1,343, or 65.8 per cent, would have been preventable "if the care of the woman had been proper in all respects." By a careful review of every death that occurred the committee established to the extent possible the factor or factors that were responsible for the fatality.

Responsibility for the occurrence of the 1,343 deaths which the committee adjudged preventable was distributed among physicians, patients and midwives. To the medical group 61.1 per cent of the preventable deaths are charged. The patient is held responsible for 36.7 per cent of the deaths, and the midwife for 2.2 per cent of the total of these deaths.

These figures, startling as they are, do not however, in the judgment of the committee give a reasonable picture of the problem. Hence the report of the committee devotes much attention to the various factors affecting puerperal mortality, such as the widespread use of anesthetics, the decline in spontaneous deliveries, the greater frequency with which operative measures are employed cesarean sections, hospital and home deliveries, prenatal care, economic status, and a score of other important items.

"Sixty per cent of all deaths," the committee state in its report, "which could have been avoided have been brought about by some incapacity in the attendant: lack of judgment, lack of skill, or careless inattention to the demands of the case. Some of these situations have arisen out of the fact that interns have been given too wide a field of independent activity. Most are plainly the results of incompetence. Prevention in this field will mean increasing the respect of the physician for the gravity of obstetrical operations and educating him to greater caution in attacking problems which are properly the field only of the highly trained obstetrician."

ANESTHESIA

In the detailed study of the factors that influence maternal mortality, the committee finds that the use of anesthesia during labor and delivery has grown steadily in extent since its introduction in the last century and is a problem of the most pressing importance, more so in the United States than in any other country. This has come about to a large extent through pressure from the lay public. The women of the large urban centers have become steadily more insistent in their demands for shorter and less painful parturition, and the accoucheur may disregard these demands only at great risk to his own practice.

"The wide effects of the increased use of anesthesia can only be guessed at, but the direct effect of the administration of the anesthetic in its tendency to lessen and enfeeble the expulsive powers of the uterine musculature must be reflected in an increased necessity for artificial assistance at delivery. The frequent use of instrumentation is based upon the easy accessibility of anesthesia. It is the opinion of many observers that the increase in the use of anesthesia is a factor in keeping the maternal mortality rate stationary."

OPERATIVE DELIVERY

The committee finds that a prominent feature of the development of modern obstetric practice has been a steady increase in the proportion of operative deliveries. According to authori-

tative estimates, not more than 5 per cent of all delivery cases require operative intervention. A study of the records of sixty-seven hospitals in which almost 75 per cent of all hospital deliveries occur shows that operative intervention is practiced in 24.3 per cent. In the city as a whole it is estimated that one out of every five deliveries is an operative delivery. In comparing the maternal deaths in operative deliveries and those in which the delivery was spontaneous, the committee found that the maternal mortality was five times as high among the operative deliveries as among the spontaneous ones.

In commenting on this finding, the committee states: "That the increase in the use of instrumentation brings with it an increased hazard is evident if the relative rates for spontaneous and operative delivery are examined. We cannot disregard the enormous difference between them. The death rate for spontaneous deliveries is less than one-fifth that for the operative. Clearly this represents a serious defect in the management of these cases."

"It is not contended that the rates can be made equal. The necessity for operative interference arises, at times, out of serious abnormalities or disturbances of the mechanism of labor, which, in themselves, greatly increase the hazards. But any such disparity as that shown in these figures is a certain indictment of those undertaking the interference."

The committee believes that "a reduction of the mortality rate can be achieved through a reduction in operative interference."

"Increasing demand on the part of the patient for shorter and less painful parturition (delivery), the greatly increased use of anesthesia, the spread of the knowledge of surgical techniques, and the pressure of time upon the attendant," the committee believes, "is responsible for the increase in operative deliveries."

CESAREAN SECTION

While all surgical maneuvers have increased in obstetrics, the incidence of cesarean sections has increased notably. In 1910 in one of the large New York hospitals, only 2 in 1,000 deliveries were made by cesarean section. In 1927 the number increased to 25.

The committee finds that the incidence of cesarean sections in the hospitals of the city is high. While 2.2 per cent of all deliveries were made by cesarean section, this operation was responsible for almost one-fifth of all the deaths.

HOSPITAL AND HOME DELIVERIES

A little less than 30 per cent of all deliveries studied during the three year period took place in the home. During the same period but 14.5 per cent of the 1,343 preventable deaths followed delivery in the home. The relative death rate per thousand live births for hospital and home deliveries is therefore 4.5 per thousand live births in the hospital and 1.9 per thousand live births in the home. The maternal mortality rate for home deliveries is therefore substantially less than half of that in the hospital deliveries. However in evaluating these figures it should be remembered that only those deliveries which are unassociated with serious abnormalities are usually undertaken in the home. When the labor becomes unduly prolonged or serious accidents occur in its course or the prognosis is unfavorable, the case is either referred to or transferred to the hospital. The record of hospital deliveries is therefore deeply affected by the selected nature of the cases in which delivery occurs at home.

In reviewing the matter, however the committee observes that "the great increase in the hospitalization of the normal parturient has failed to bring the hoped-for reduction in puerperal morbidity and mortality, and thus in spite of great advances in our knowledge of the processes involved and the proper way of treating them. It would seem that the present attitude toward home confinement requires re-examination, and a program looking toward an increase in the practice of domiciliary obstetrics deserves careful investigation."

ECONOMIC STATUS AND MATERNAL MORTALITY

The economic status of the prospective mother the committee's studies reveal, appreciably affects her well being and the safety with which she may expect to pass through the birth experience. In making a detailed study of 341,879 births that occurred in the three year period under consideration, and divid-

ing the mothers into four groups designated respectively A, B, C and D. A representing the slum population, B the depressed economic artisan class, C the so-called white collar group and D the group most favorably situated economically, it was found that their comparative maternal mortality based on figures (which excluded the deaths following abortion and ectopic pregnancies) were as follows: 49 deaths per thousand live births for the slum population, 42 in the artisan group, 46 in the white collar class, and 39 in those most favorably situated economically. The difference between the extremes, group A and group D, is therefore 20 per cent.

MIDWIFE PRACTICE

While approximately 10 to 12 per cent of the births in New York City and throughout the country occurred under the supervision of midwives, the committee finds that provision for the proper education, registration and supervision of midwives is exceedingly inadequate in most states in the Union. Two schools for midwives are in operation in New York City. However, the committee found that "a large number of the practicing midwives in New York City are foreign-born women who were trained in the country of their birth and came to this country and began the practice of midwifery before the present laws regarding licensure were put into effect." New York City has at the present time 863 licensed midwives. These attend approximately 10 per cent of the annual births.

The committee interviewed fifty-nine midwives who had either delivered or been in contact with a patient whose case ended fatally. Of the fifty-nine midwives interviewed, nineteen were adjudged by the committee to be competent, twenty were thought to be only fairly competent and twenty were incompetent. When judged on the basis of their obstetric results, the record of midwifery deliveries compared to deliveries by physicians, the committee found "that there is no great disparity between the results of the work done by the two groups."

In reviewing the problem of midwifery which in the United States has been regarded until recently as a necessary evil to be done away with as soon as possible, the committee states that "contrary to the generally accepted opinion, the midwife is an acceptable attendant for properly selected cases of labor and delivery. There has never been a contention that she has any place except for the normal delivery at home, but we have seen that her results are as good as those obtained by the physician under what are justly regarded as comparable circumstances and for comparable cases."

"Of the midwives seen and interviewed it is significant and must be borne in mind that less than a third were judged to be competent and in the face of incompetence or only fair training and ability the results were by no means prejudicial to the midwife."

Proper training is the first requisite and there is an increasing tendency among part of the medical profession to see that it is provided. After proper training there must be suitable, adequate and cooperative supervision and control of that practice.

The midwife should have a position in the scheme for providing maternity care. It remains for the medical profession to define what that position should be. She is able to supply attendance and nursing care for a smaller compensation than the costly training of a physician requires, but the necessity for every woman to have adequate care during pregnancy and at delivery, and to have the services of a physician if and when those services are needed, must be kept in mind.

It is necessary first of all to provide midwives who are properly trained. It would not seem absolutely necessary that a nurse's training be a prerequisite to training as a midwife, but in order to extend the practice of employing midwives as accoucheuses in normal parturition a different type of woman must be brought into the field. The present type of non-nurse midwife would prove wholly unacceptable to certain classes of the community. While the only slightly educated woman with adequate training may be a capable midwife, the more educated patient will demand a different type of attendant. The two groups need not be mutually exclusive. There should be opportunities for both to receive the necessary training.

The midwife should be encouraged and if necessary required to return for short courses a certain interval. Her training

must prepare her to understand the mechanisms of normal labor and delivery. She must be able to detect the signs of the abnormalities of pregnancy, and she must be able to measure the pelvis accurately. She must be thoroughly familiar with a simple method for maintaining asepsis. Finally, she must be equipped to give suitable care to both mother and infant during the puerperium.

The medical profession must accept the midwife as one of its adjuncts. Physicians must make themselves responsible for her proper training and supervision as such. They must regard her as an ally in the effort to reduce the morbidity and mortality associated with childbearing. Both officially and privately there must be an alteration in the prevailing attitudes toward her. There must be a readiness to cooperate with her to insure the results both physician and midwife are anxious to achieve."

CONCLUSIONS AND RECOMMENDATIONS

The committee ends its report with a number of concrete recommendations.

"To improve this situation and remove the causes out of which it arises it is evident that there must be a determined effort to educate both the lay public and the medical profession to an understanding of the necessity for change in certain of the methods now employed. The profession itself must accept the responsibility for educating the lay public to a better understanding of the aims of obstetrics and the methods by which those aims may be realized. But prior to that must come increased education of the profession, that it in turn may wisely inform the lay public."

First, a prospective mother must have further instruction in the necessity for prenatal care. She must be taught that prenatal care does not mean merely registering for confinement, that it is imperative to obtain that care as early as pregnancy is suspected, that one visit at which no abnormalities were discovered is no guaranty of continuing good health but that regular return for observation is vital if her attendant is to be enabled to give her the best possible care, that previous normal pregnancies and deliveries do not assure subsequent normal ones, that proper and sufficient prenatal care offers her the greatest assurance of an uneventful confinement.

"Furthermore, some information must be made available to the patient as to the standards of such prenatal care. She should have some knowledge of the purposes of such care and what she may expect from her attendant as the minimum requirements of a proper prenatal supervision. She should know that the omission of urinalysis, blood pressure determination, or the measurement of her pelvis constitutes negligence, that a thorough physical examination is a necessary part of proper care. She must be informed of the possible gravity of symptoms that seem to her mild, and the fact that early treatment is the prerequisite to the prevention of later trouble."

"The medical profession is obligated to inform the lay public that operative delivery undertaken merely to alleviate pain or shorten labor involves increased risk for both mother and baby."

"The relative safety of delivery at home should be emphasized. Effort should be made to induce women who cannot obtain adequate medical or hospital care to avail themselves of the services of qualified midwives under the supervision of physicians."

"To accomplish this education the medical profession must assume a role which heretofore has been left to lay organizations. Confidence of the lay public in the medical profession will enable this to be done with greater authority and increased chances of success."

To do this well the outstanding members of the profession in every community must actively interest themselves in the process. Obstetrical societies would do well to use the channels of the press and radio to broaden the sphere of their activities in this line. They would further increase their educational function by issuing authoritative pamphlets from time to time. They must assume responsibility for the teaching given through social service and lay organizations.

Hospitals in order to qualify for recognition by the controlling authorities must have qualified obstetricians as directors or their staff. The hospital must maintain a special

clinic for prenatal care, in charge of a member of the visiting obstetrical staff. There must be a sufficient number of beds set aside for the hospitalization of clinic patients with complications. There must be a social service department adequate, as to training and personnel, to keep in touch with all patients, to insure early registration and regular attendance, to facilitate the patients' cooperation through home adjustments, to assist in the educational function of the hospital to the community.

All hospitals must maintain separate delivery rooms where only obstetrical cases are treated. The rules for the maintenance of asepsis must be rigid including masking, the importance of which deserves reemphasis. Labor rooms must be sufficient to insure their availability to all patients. Isolation must conform to the most stringent regulations and include proper technique on the part of the nursing staff. All nursing must be done by properly supervised nurses, who should be especially trained in obstetrical nursing. The resident staffs must be under supervision at all times. There must be an invariable rule requiring the responsible attending physician to see patients promptly and supervise directly the residents who are assigned to them. Furthermore, the less experienced members of the staff must be under supervision of the responsible heads.

"Proprietary hospitals should be brought under the supervision of a responsible board of hospital control and unless they provide adequate facilities as described above except for prenatal care and social service, they should not be permitted to accept obstetrical patients.

"The situation in regard to midwives must be altered. More schools are needed for their training, including both women who have had previous training as nurses and those who have not, effort should be made to enroll types of women who would be acceptable to groups of the population now unwilling to employ a midwife, and the nurse wife is suitable for this purpose. Licensure should be based upon examination. Additional short courses, at stated intervals, should be compulsory. Supervision should be increased, and changed to include actual oversight of cases under care. With physicians in charge appropriately trained nurse-midwives might make suitable supervisors. Midwives should be required to report births within forty-eight hours, to report immediately any abnormality during labor, and to call consultation if labor continues beyond a definite time limit. The physician must be prepared to give the midwife unqualified cooperation. Some hospitals might well make use of midwives to conduct the deliveries in their outpatient service, under the direction of the inpatient obstetrical department.

"The hazards of childbirth in New York City are greater than they need be. Responsibility for reducing them rests with the medical profession."

Malpractice Failure to Remove Sponge After Tonsillectomy—The defendant a physician, removed the plaintiff's tonsils, Oct 18 1927, under a general anesthetic. After the operation, the plaintiff had a severe cough, pain in the left chest peculiar expectoration, and fever. About Jan 1, 1928 the plaintiff consulted another physician, who found a lung abscess. Among other efforts to be cured the plaintiff went to a clinic in Philadelphia where, by successive operations a hole was burned with a cautery through the pleura and into the lower lobe of the lung to drain the abscess. Feb 2, 1930 during a lung hemorrhage, the plaintiff coughed up a batting sponge. Attributing the presence of the sponge to the defendant's negligence, the plaintiff sued. The trial court directed a verdict for the defendant, and the plaintiff appealed to the Supreme Court of Michigan. The defendant-physician testified that gauze sponges were used by him during the tonsillectomy; the plaintiff's testimony was to the effect that they were of batting. In the operation in Philadelphia, said the court gauze was used and if any batting was used in the treatment to swab the wound, it would normally be discharged by way of the wound and would not be coughed up. In removing tonsils there is danger of foreign and infected matter getting into air

passages of the lungs, especially by gasping and heavy breathing of the patient, and a natural result thereof is lung abscess. On the question of whether the verdict was properly directed against the plaintiff, said the Supreme Court the evidence must be viewed in the light most favorable to her. The record shows that the plaintiff coughed from the lung a batting sponge. How did it get into the lung? There was evidence negating its getting there during the operation in Philadelphia, and, continued the court, the jury would be justified in so finding from the record. Furthermore, the jury might find the remaining opportunity to be in the operation done by the defendant. Such a finding might have support in the element of time, for the lung abscess a natural result of the entry of the foreign matter into the lung, followed the operation performed by the defendant. If this be the finding said the court then this is not a case where losing the sponge was observed and prompt and proper effort made to remove it, but a case where the sponge was lost unobserved and negligently, and the case stands on a par as regards negligence with those cases where sponges have been left in incisions. The rule said the court in such cases is stated in 21 R C L 388.

Probably the most common instance of malpractice which is brought into the courts arises out of surgical cases where the physician or attendant has left a sponge in the wound after the incision has been closed. That this is plainly negligence there is no doubt at all, and it matters not at all that many physicians testify that the best of surgeons sometimes leave a sponge or some other foreign substance in the bodies of their patients for this is testimony merely to the effect that almost every one is at times negligent. Whether the particular act was negligent is for the jury to decide after considering the circumstances of the case.

The question of negligence, therefore was held by the Supreme Court to be for the jury and the trial court erred in entering a directed verdict for the defendant. The case was remanded for a new trial—*McKinstry v Matthees* (Mich), 247 N W 73.

Evidence When Opinion of Expert Witness Invades Province of Jury—An expert witness may express an opinion as to whether or not a physician has been guilty of malpractice by commission or omission. On the ultimate issue of whether a patient's condition resulted solely from malpractice however an expert witness invades the province of the jury when he goes beyond stating that the condition *could*, and in saying that it *did* so result. Such an opinion is but the private judgment of the witness and is not competent evidence. Whether the alleged malpractice could cause the result complained of is a question of science only. Whether the malpractice did occasion such result usually a matter of controversy, is not a question of mere science. When a result could have been occasioned by one of two or more causes, the ultimate fact of which cause occasioned the result is for the determination of the jury. A medical expert may not in case of conflicting evidence invade the province of the jury and testify that the result was in fact occasioned by one cause only—*De Groot v Winter* (Mich) 247 N W 69.

"Imbecility of Mind" Defined—The term 'imbecility of mind' says the Court of Appeals of Kentucky, is not susceptible of exact or comprehensive definition. It is generally applied to indicate a mental condition between feeble-mindedness and idiocy. Mental imbecility consists of the absence of or change in the faculty of reasoning and discerning, which renders a person incapable of taking care of himself and administering his affairs—*Doming v Siddens* (Ky) 57 S W (2d) 1.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American J Obstetrics and Gynecology, St Louis

Vaginal Retractor for Operations on Cervix. J. S. Diasio. New York—p. 278.

Nephritis in Pregnancy.—From a follow-up study of a large series of pregnant patients in whom the diagnosis of nephritis was established Stander concludes that the prognosis is grave, the average maternal mortality occurring within ten years being approximately 40 per cent. It is his belief that the strain of the pregnancy on the function of the kidneys greatly aggravates an underlying chronic nephritis and thereby materially shortens the life of the patient. To help in the early recognition of nephritis he advocates the employment of the urea clearance and fifteen minute phenolsulphonphthalein tests. The creatinine excretion test may also be employed although it perhaps measures the tubular instead of the glomerular function. In addition to these tests the patient's past history, the duration of pregnancy, the behavior of the blood pressure, albuminuria and edema under hospitalization with proper dietary measures, the examination of the eczema, the cardiovascular system and blood and urine chemistry are all aids in establishing a correct diagnosis. The best treatment for chronic nephritis in a pregnant woman is the termination of the pregnancy and the prevention of any further pregnancy.

Aschheim-Zondek Reaction in Chorionepithelioma.—Mazer and Edeiken point out that abnormal uterine bleeding following a normal or a mole pregnancy should not be treated by radium because it masks the local symptoms of chorionepithelioma. It is impossible to make an early diagnosis of

chorionepithelioma by means of uterine curettage. The authors present two cases of chorionepithelioma which show by contrast the value of the Aschheim-Zondek reaction in the diagnosis and the prognosis of the disease. The source of the hormone prolactin, responsible for the Aschheim-Zondek reaction is living chorionic epithelium, which should not persist longer than two weeks after the termination of a normal pregnancy or eight weeks after expulsion or operative removal of a mole pregnancy. The quantity of prolactin excreted is proportional to the amount of abnormal chorionic epithelium present, hence a gradual increase in prolactin excretion accompanying abnormal uterine bleeding following the termination of a normal or a mole pregnancy is indicative of a proliferative process, chorionepithelioma. Persistence of the Aschheim-Zondek reaction after extirpation of the uterus for chorionepithelioma points to metastasis, which should be located and treated by means of intensive irradiation. Prolactin is probably a placental hormone and exerts its influence on the ovaries through the medium of the anterior pituitary lobe. The degree of ovarian response in chorionepithelioma is variable, depending on intrinsic ovarian conditions and the responsiveness of the anterior hypophysis to prolactin stimulation.

Female Sex Hormone and Blood Coagulation of the New-Born.—Hirst proposes to show the effect of certain standardized preparations of estrin on normal new-born infants and on several abnormal infants, including one case of moderate hemophilia. The study of each group consisted mainly in noting the duration of bleeding without pressure from heel punctures, and the time required for coagulation of blood drawn into uniform machine-made capillary tubes. He found that the normal coagulation and bleeding times of both male and female new-born infants are nearly constant between three and a half and four minutes for the first eleven days. The injection of solution of crystallized estrin (theelin) produced a moderate reduction of the blood curves in normal male and female infants. Injections of progynon were followed by a definite increase of the bleeding and coagulation times in normal new-born infants of both sexes. Abnormally long coagulation and bleeding times, as well as spontaneous bleeding other than vaginal, were corrected by injections of theelin. Breast engorgement in both sexes was produced by injections of female sex hormone indicating a direct effect of estrin on the breasts of new-born infants rather than an indirect result through the activation of a prepituitary specific hormone. Vaginal (uterine) bleeding was initiated by estrin administration. Icterus neonatorum appeared to clear up more rapidly than usual, under injections of theelin. The author is ascertaining whether icterus may be prevented by the early administration of estrin.

Intra-Abdominal Radiation in Advanced Carcinoma.—Schumann outlines a procedure designed to further the attack on advanced pelvic carcinoma by applying roentgen rays directly to the affected tissues without the intervention of the abdominal parietes. The patient under tribrom ethanol anesthesia is placed in the lithotomy position, biopsy is performed, the nature and extent of the carcinomatous infiltration are determined by bimanual examination and 50 mg. of radium is applied to the cervix or to the uterine cavity with such filtration as is deemed appropriate for the individual case. Then in the Trendelenburg position the abdomen is prepared for laparotomy, a median incision from 6 to 8 inches in length is made and the abdominal walls are widely separated by means of a Balfour retractor. The intestine is carefully walled off with a large gauze pad after which the abdominal wall and all the pelvic tissues except those involved in the malignant growth are protected from irradiation by being covered with sheet lead 2 mm. in thickness. Strips of lead are cut to fit the interior of the abdomen and are then snugly molded into position with the fingers so as to isolate the tumor area; all other tissues are covered by strips of lead. A large sterile dressing is then applied and the patient is given a full therapeutic dose of roentgen radiation, 1 to 1.5 milliamperes at a distance of 18 inches, 150 kilovolts, 6 mm. or aluminum filtration. On the completion of the treatment the sterile dressing is replaced, the lead and gauze packs are removed and the incision is closed. No attempt is made to remove any of the malignant tissues. The author has performed this operation on three women without any postoperative complication or any particular discomfort to the patients.

*Pleurisy in Rheumatic Fever Clinical Observations W K Myers and E B Ferris Jr Boston—p 325

Benign and Malignant Neutropenia—Beck reports four cases two of primary malignant neutropenia as described by Schultz, one of primary subchronic recurring benign neutropenia, and one that began as a fulminating case, with recovery and three months later recurred as a primary subchronic benign neutropenia. These patients did not give a history of exposure to any of the physical or chemical agents known to produce benign or malignant neutropenia, nor did they give a history of any previous infection that might have had a bearing on the disease. The clinical picture at the inception of the illness was the same for all four patients, in the patient with the typical subchronic recurring benign neutropenia, the onset was more gradual. These cases suggest that there is a fundamental difference in the pathologic changes underlying the recovered and the fatal cases. In the fatal cases, the maturation of granulocytes had ceased and the granulopoietic tissues were exhausted. A maturation factor for granulocytes has not yet been discovered, so that a specific treatment could not be applied. In the recovered cases maturation was arrested and the granulopoietic tissues were not exhausted the fault seeming to be in the lack of a chemotactic factor to call the granulocytes to the circulating blood. In one of the two cases of primary malignant neutropenia, the roentgen rays in some unknown way stimulated this function to normal. Dorn's theory is that the roentgen rays bring about a destruction of some of the intact myeloid foci with a liberation of autogenous nucleotides, which then initiate the maturation and delivery of granulocytes from the remaining myeloid foci. In the patient with the typical subchronic recurring benign neutropenia, which was more mild, this function righted itself in time to prevent irreparable damage.

Absorption of Dextrose by Rectum—In determining whether or not dextrose can be absorbed by the rectum, Collens and Boas observed that in the nondiabetic group there is a rise in the blood sugar ranging between 16 and 25 per cent and that the amount of dextrose recovered at the end of the experiment varies between 10 and 27 per cent at the end of two hours. This indicates that as much as 90 per cent of the dextrose administered by rectum was absorbed. In the diabetic group much the same picture prevails except for the fact that two patients showed no rise in the blood sugar, and one even experienced a 20 per cent decrease. The other four diabetic patients had elevations in the blood sugar of 9, 21, 38 and 50 per cent. All, however, showed evidence of absorption by the analysis of the rectal return. In the patient in whom there was a decrease in the blood sugar, only 14 per cent of the amount administered could be recovered at the end of two hours. The authors present further evidence that dextrose is absorbed in significant quantities by the fact that a diabetic patient, who had recently experienced an attack of hypoglycemia as the result of an overdosage of insulin, was immediately relieved by the administration of 25 Gm of dextrose by rectum. The authors' series consisted of twenty-four nondiabetic patients, eleven of whom received 250 cc of a 10 per cent solution of dextrose (25 Gm), seven 250 cc of a 25 per cent solution of dextrose (50 Gm), five, 400 cc of a 5 per cent solution (20 Gm) and one, 200 cc of a 50 per cent solution (100 Gm). Two of the diabetic

patients received 250 cc of a 10 per cent solution of dextrose, two, 200 cc of a 25 per cent solution (50 Gm), and three, 400 cc of a 5 per cent solution. At the end of two hours the patients were given an enema with 500 cc of tap water, and the evacuation was collected. These returns were analyzed for the dextrose content by the Benedict quantitative method for estimation of sugar in the urine.

Pleurisy in Rheumatic Fever—Myers and Ferris observed fifteen patients suffering from rheumatic fever with pleural lesions. Thirteen had rheumatic pleurisy, three, fibrinous pleurisy, and ten, pleurisy with effusion. Two patients had bilateral hydrothorax due to myocardial failure during the acute stages of rheumatic fever. Involvement of the pleura was characterized by the sudden onset and by dyspnea, orthopnea, mild cyanosis pain (depending on the nature of the pleural lesion) and a febrile response varying in severity and duration. Evidence pointed to concurrent pulmonary lesions in the patients who had true rheumatic pleurisy. The pleural lesions were found to be independent of pericarditis and were related to underlying pulmonary processes. The hemorrhagic nature and the readiness with which clot formation took place characterized the fluid of rheumatic pleurisy. Polyarthritides preceded by involvement of the pleura and lung in two instances. Silicosis did not alter the course of the pleural and pulmonary lesions and, indeed, failed to relieve completely the articular symptoms in the presence of an extension of the rheumatic process to the pleura and lung.

*Protein Extract of Vitreous Humor (Bovine) Preliminary Report. C Hobart St Louis—p 237

Ophthalmic Tuberculosis—Since 1926 Nakamura, in the treatment of ophthalmic tuberculosis, used AO, a tuberculosis vaccine discovered by Arima and Aoyama. He states that 1 cc of AO number 1, 1 cc, the smallest dose for adults, administered once a week, nearly always brought about a subsidence of the disease without any noxious result. He believes that ophthalmologists should extend the method of using the optimal dose not only in the treatment of phlyctenae but also in all tuberculous diseases of the eye. He points out that AO has proved to be the best remedy in all forms of ophthalmic tuberculosis as compared with other tuberculins. Of the 503 cases in which accurate observations were made, the conditions subsided in 89.5 per cent, and in 10.5 per cent the conditions remained unchanged. These diseases were tuberculous, were suspected of being tuberculous, were not certain etiologically or defied antisyphilitic treatment. The author concludes that the great advantage of AO is that, used in nonincreasing doses as he has advocated, it never creates unfavorable results.

Removal of Lid—Hughes removed a tumor that had invaded the inner two thirds of the lower lid with the diathermy cutting current, making the section in the normal tissue. The tumor was thus removed in its entirety without being cut and without the use of forceps. The margin of the free end of the lower lid was denuded for about one eighth inch (0.3 cm) and a similar portion of the margin of the upper lid was denuded. A double armed suture was passed through a rubber pig and through both lids, and this was passed through a second pig and tied stretching the remaining lateral third of the lower lid. This covered almost all the lower part of the cornea, keeping the remnant of the lower lid from contraction and preserving its normal shape. An adhesion was thus formed between the upper and lower lids at the point of denudation. At the same time a pocket was made in the upper lid preparatory to the insertion of a piece of mucous membrane from the mouth. A piece of mucous membrane was then removed from the inside of the

cheek and attached to a small metal form with its smooth surface toward the form, later this formed the conjunctiva of the new lower lid. A perforated piece of cellulose acetate to which a small amount of sterile petrolatum was applied was placed directly over the lids and the denuded surface inferiorly. A pressure dressing of gauze fluffs was then applied and left in place for one week. At the first dressing the rubber pigs and the suture were removed, and the pressure dressing was reapplied to remain for five days more. A light dressing, changed every three days was kept on until three weeks after the operation. The granulation tissue was removed to form a clean bed to receive the graft from the upper lid. The skin of the upper lid, including the part lined by mucous membrane, was then removed. The mucous membrane edge was sutured to the conjunctiva and the edges of the skin were approximated by fine interrupted black silk sutures (number 00 special ligature braided silk). A pressure dressing consisting of perforated celloid moistened with petrolatum was applied directly over the eyelids and graft. The gauze fluffs were held in place with adhesive tape and then pressed firmly down by means of a tight bandage and adhesive tape. A week later a similar dressing was applied for another five days. After that a light dressing was applied until, at the end of three weeks dressings were dispensed with. The intermarginal adhesion was left intact for six weeks, which allowed full contracture to take place before it was cut. When it was cut, the intermarginal adhesion on the lower lid assumed a relatively normal position.

Protein Extract of Vitreous Humor—Hobart states that his clinical observations and tests prove that certain persons are hypersensitive to vitreous humor protein and that in such persons a characteristic inflammatory reaction results when a loss of vitreous occurs through injury or operation. Persons with cataracts or any injury of the globe should have an intradermal test with vitreous protein before operation. Persons who are hypersensitive should be desensitized. Following extraction of a cataract with loss of vitreous but with retention of the cortex, a person may be hypersensitive to both proteins. A person hypersensitive to the vitreous protein of the ox or of the pig is also hypersensitive to the protein of his own vitreous. It is possible to sensitize an animal to its own vitreous protein. Regardless of the amount of vitreous lost, some persons have a severe reaction, others a mild and still others no inflammatory reaction. The author hesitates to recommend or suggest the dosage for purposes of desensitization. It will vary according to the patient. It is best to begin with about 1 cc and gradually to increase the dose to 2 cc. In order to determine whether the patient is desensitized, an intradermal test should be performed.

New Method of Treating Fractures of the Lower Extremity L H Oetjen Leesburg—p 69

Fractures of Lower Extremity—Oetjen describes his well leg traction method for treating fractures of the leg. The first cast to be applied is on the well leg and is applied in the usual manner extending from the mid thigh to several inches beyond the toes. The foot should be placed at right angles to the leg and should be held in slight eversion and care should be taken that the plantar surface of the cast is firmly reinforced so as to support the weight of the lower traction. The ankle of the fractured leg is then prepared in the usual manner. The site of election for the traction of the Steinman pin is at a point two to three inches above the internal malleolus. The

skin and periosteum on each side is infiltrated with a 2 per cent solution of procaine hydrochloride and the pin is inserted without any drilling or preliminary skin incision. Sterile sponges are then placed next to the skin over the ends of the pin. The leg is wrapped with cotton batting and the plaster cast is applied, including the toes and several inches beyond. The traction stirrup is placed over the ends of the pin and the stirrup incorporated in the cast with plaster bandage. After the plaster has firmly set the splint is bolted together and the traction nut screwed down and correct alignment of the fragments is obtained by either internal or external rotation of the fractured leg. In general the author's time for the removal of the pin is: fractures of the pelvis, from four to six weeks, fractures of the neck of the femur, from twelve to fourteen weeks, intertrochanteric fractures, from seven to nine weeks, subtrochanteric fractures, from seven to ten weeks, fractures of the femoral shaft from five to ten weeks, fractures of the distal third from five to ten weeks, fractures of the tibia, from four to twelve weeks, and operative cases, from six to eighteen weeks.

Alimentary Intoxication in Infants—Cohen and his associates treated nine cases of alimentary intoxication with the continuous intravenous drip and starvation in an attempt to correct dehydration to reestablish diuresis and to restore the chemical equilibrium of the blood serum. They found the administration of dextrose and saline solution by continuous intravenous drip to be a reasonably safe procedure. Dehydration is rapidly corrected and diuresis reestablished. Adjustment of inorganic equilibrium of the blood may require several days. Clinical improvement usually precedes chemical readjustment. Diarrheal acidosis in their cases was due either to a relative or an absolute increase in the chloride or to a decrease in fixed base in agreement with previous observation. Increase of non-protein nitrogen disappeared promptly with the reestablishment of diuresis. The authors draw no final conclusions as to the therapeutic value of this method of administration because of an insufficient number of cases. The amount of fluid required to overcome dehydration would seem to be less than when other channels of administration are used. There is real danger of producing edema because of rapid blood dilution.

Pseudohypertrophic Muscular Dystrophy—Mettel and Slocum confirm the work of Milhorat Technor and Thomas who have shown that patients presenting pseudohypertrophic muscular dystrophy show a creatinuria even when maintained on a creatine free diet. The normal subject excretes ingested

creatinine almost quantitatively (from 65 to 100 per cent). The inability to retain ingested creatinine is said to be in proportion to the severity of the disease. The authors present the case histories of three patients suffering from pseudohypertrophic muscular dystrophy who were treated with glycine. An earlier report showed that the daily ingestion of 5 Gm. of glycine was followed by a definite rise in the creatinuria. The daily administration of from 15 to 20 Gm. of glycine increased the daily excretion of creatinine to from 300 to 500 mg. After a period of some weeks (depending on how advanced was the case), the creatinuria begins to decrease despite the continuance of glycine until it falls to the former control level. Coincident with the increase in creatinuria there is an improvement in the patient's ability to hold ingested creatinine. These changes in the metabolism disappear in the course of a few weeks after the cessation of glycine ingestion and return if the administration is again instituted. The first symptoms of improvement are manifested by a curious feeling in the muscles which the patients described as a crawling, rumbling sensation. Following this there is a disappearance of the sensation of fatigue. Gradually the function of the involved group of muscles is so improved that activity can be performed which had been impossible before the administration of this drug. Two of the patients so treated showed improvement, the other one showed slight improvement.

Cultures of Urine for Tubercle Bacilli.—Seidman took cultures of eighty-nine tuberculous specimens from forty-five patients, eighty-one of which were either bladder or kidney urine. Tubercle bacilli were isolated from sixty, or 67.4 per cent, of the specimens and from thirty-nine, or 86.6 per cent, of the patients. In fourteen of the positive cultures, no acid fast bacilli had been seen in the direct smear of the concentrated sediment. From fourteen specimens, in which acid fast bacilli had been seen in the direct smear, no growth was obtained. In fifteen specimens, in which both culture and direct smear were negative, the inoculated guinea-pigs developed tuberculosis. Growth of tubercle bacilli was obtained on Corper's crystal violet potato cylinder from 54 per cent of the positive sediments, on Petroff's coagulated egg medium (without gentian violet) from 60.1 per cent and on Sweeney's milk meat infusion egg and cream medium from 71.6 per cent. Oxalic acid 5 per cent, and sodium hydroxide, 3 per cent, proved better as digestants than a 6 per cent solution of sulphuric acid, both in the percentage of isolations and in the average time required for the appearance of growth. All three reagents were equally efficient in destroying secondary contaminants. The shortest interval for the primary isolation of tubercle bacilli by culture was sixteen days. Growth was obtained within three weeks in 18.3 per cent of the positive specimens, on 7 per cent of the inoculated culture tubes. For the reasons discussed, guinea-pig inoculation still appears to be superior to cultures for the diagnosis of tuberculosis in suspected cases. No avian strains of tubercle bacilli were recovered. Strains from eighteen cases were of the human type, and the remainder showed the growth characters of the mammalian organisms.

Prevention of Blood Clots in Bladder.—During 1932 in the course of investigations directed toward satisfactory suture of the bladder neck during suprapubic prostatectomy, McLellan felt that the problem could be greatly simplified by the use of some solution that would prevent the formation of blood clots in the bladder. Sodium citrate solution immediately suggested itself. Since that time the author has used the 3 per cent solution of sodium citrate as a routine in forty-three operations for enlargement of the prostate, viz., twenty suprapubic prostatectomies with closure of the bladder neck, nineteen resections of the prostate under vision, and four Craik cautery punch operations. During prostatectomy the solution is injected into the bladder as soon as the bladder neck has been sutured. Approximately 25 cc. is left in the bladder until the suprapubic wound has been properly closed, then this solution is washed out and replaced by about 25 cc. more and the tube clamped while the patient is taken to his bed for permanent drainage under low decompression. If the outflow is bloody, the citrate solution may be changed again several times during the first few hours. The author states that the use of this solution has completely eliminated the formation of clots and the plugging of the catheter by such clots in every instance. All clots must be removed from the bladder before the citrate solution is injected, as it may not disorganize rapidly any clots that are already formed.

Diphtheritic Urethritis.—Berry reports a case of diphtheritic urethritis in a man aged 45, who complained of frequent painful urination with two attacks of retention. The condition had been present for about three weeks and just prior to its onset he had had a left ureteral colic and passed a calculus the size of a shriveled grain of wheat. Hot sitz baths and sedatives were prescribed and the patient was instructed to return in a week. He returned in five days with a temperature of 101 F. and a pulse of 100. There was marked edema of the penis, which was red and painful. The membrane appeared exactly as before. Bacteriologic investigation finally revealed a true diphtheria bacillus. Antitoxin was administered 15,000 units during the first week and 5,000 each for two following weeks. The membrane, which had been densely adherent for nearly a month, began to loosen the morning after the first injection and came away in large pieces in the urine. In three days the normal urethral mucosa could be seen shining through and pieces of membrane could be picked off with forceps though it was still adherent and left a bleeding surface. In ten days the urethra was clear of membrane though the mucosa was inflamed and remained so for weeks. The areas of induration about the urethra eventually went on to suppuration and required incision. They finally healed completely. One year from the original onset of his illness he returned with a condition similar to that of the previous year. Culture showed the same organism as before. Antitoxin was again administered in doses of 5,000 units with out benefit and the dosage was increased to 15,000 units, but still the disease progressed. The meatus became widely eroded and the membrane extended to the frenum which was destroyed. A large perurethral abscess again formed at the penoscrotal junction, it opened widely and through it the greater part of the urine found exit. In view of the fact that cultures had always shown the same diphtheria-like organisms, 40,000 units of antitoxin was administered. The patient had a chill and a marked febrile reaction with immediate improvement in his condition. The antitoxin was repeated at intervals of five days for three weeks and he now appeared well. All the areas of ulceration were healed though the perurethral fistula was still discharging. After the second dose of antitoxin a cystoscope was passed in order to dilate the urethra and to ascertain the extent of the involvement. This showed the condition to be limited to the anterior urethra, the posterior urethra and the bladder were entirely normal and the urine from each ureter was sterile. The author concluded from microscopic and cultural studies that the organism was a diphtheria bacillus although the negative virulence tests as well as the sugar reactions pointed toward an organism of the Xerosis group. The organism described in Sewell's case of chronic cavernitis resembled this organism in some respects but differed in that it was actively pathogenic for mice.

Insulin in Postpellagrous Trophic Ulcers—Sullivan reports a case in which trophic ulcers occurred following pellagra, and insulin was given to improve nutrition and thereby to hasten the reparative processes in the trophic ulcers. The trophic ulcers were the last manifestation of a fulminating pellagra of a duration of four months and appeared after the subsidence of severe cutaneous gastro-intestinal and neurologic symptoms. The pellagra had been treated by a diet rich in vitamin G and by local and general therapy for lesions and symptoms. Three months after the onset of the pellagra and after the disappearance of the pathognomonic signs the first group of bilateral, symmetrical trophic ulcers appeared on the feet. This first set of ulcers which healed in eight weeks was treated in addition to the dietary measures, by protective and antipruritic ointments and other medicaments. Two weeks later a second set of symmetrical lesions more severe and diffuse appeared on new sites on the feet and lower parts of the lower extremities. Notwithstanding energetic dietary and local treatment for six weeks this second set of ulcers enlarged the feet became indurated and inflamed and the patient steadily lost appetite and weight. Insulin was then started and in two weeks the induration of the feet had gone and the ulcers healed the appetite returned the weight increased and the paresthesias of the toes disappeared.

Reduction of Semilunar Bone—McBride's procedure consists of firmly anchoring the dorsal horn of the semilunar bone to the radius, thus restoring the effect of the dorsal ligament. When secured in this manner, the bone is in an attitude of complete dorsiflexion, which prevents it from slipping partially forward. The author believes that the success of an operation for late reduction depends on complete freedom of the ligamentous contraction and fibrous tissue attachments of the anterior horn to the radius the complete removal of fibrous tissue in the cavity formerly occupied by the semilunar bone, and of abnormal attachments of the os magnum, and the security of the semilunar bone in its normal articular bed, so that it cannot slip or rotate forward. In performing the operation an incision about 1½ inches long is made on the dorsum of the hand immediately to the ulnar side of the extensor carpi radialis. The vein and nerve, together with the extensor indicis tendon, are retracted to the ulnar side and the extensor carpi radialis to the radial side. The fibrous tissue in the bed formerly occupied by the semilunar bone is excavated and a smooth curved periosteal elevator is passed forward to free the anterior horn contraction from the radius. The bone which lies in a plane entirely anterior to the carpal bones is then prised into position by a Davis skid or a similar instrument. If it cannot be reduced without too much trauma it is better to make an anterior incision immediately to the ulnar side of the palmaris longus with its center over the radiocarpal articulation. The group of flexor profundus tendons is retracted to the ulnar side and the median nerve and palmaris longus tendon are retracted to the radial side. Complete reduction may be recognized by the contour of the dorsal horn. If the bone has a tendency to pull forward or is not entirely in alignment with the transverse plane of the wrist the anterior ligament is not entirely free in which case a crevice is made in the anterior free of the dorsal horn of the semilunar bone with a curet creating a hook into which a strand of number 00 plain catgut is inserted and sutured to the dorsum of the radius. The semilunar bone is thus checked in full dorsiflexion to the radius.

Toxic Symptoms from Ether Anesthesia—Minnitt conducted an investigation in an endeavor to find a solution for some of the mysterious problems in connection with operative procedures under ether anesthesia and to suggest a successful method of treatment. He observed that the blood sugar rises and the blood pressure falls as ether anesthesia progresses and that the blood sugar is high and the blood pressure is low when symptoms of shock are present. He believes that there is some justification for thinking that the pancreatic hormone is deficient as the result of the ketosis produced in connection with ether anesthesia. He found that the administration of insulin is a successful method of treatment for postanesthetic toxic symptoms, which are always associated with a high blood sugar that it prevents these from developing, that, on the conclusion of the operation, it eliminates the injurious effects of ether anesthesia and that during the operation, when symptoms of shock appear, and immediately before and after anesthesia it acts as a preventive against the development of toxic symptoms.

Eosinophilia of Obscure Origin—Murphy presents a case of high eosinophilia of obscure origin with interesting clinical features. There was a definite absence of tapeworm and no history of the eating of raw pork, no signs of trichinosis and nothing in the history to suggest ancylostomiasis. The patient was given 30 grams (2 Gm.) of thymol in three successive doses, with negative results. There were no symptoms of filarial infection, no localized tumor, a hydatid thrill could not be elicited in the liver, and a negative complement fixation test for echinococcus eliminated the possibility of a hydatid cyst being embedded deeply in the liver substance. Cancer of the liver could be ruled out in view of the patient's improved condition, the absence of jaundice and of any cachectic signs, and the smoothness of the liver surface. The Wassermann test was negative and there was no history of gonorrhea. The patient never had asthma, skin disease or pediculosis. The patient's excellent family history negated the possibility of inherited eosinophilia. Blood cultures, the examination for malarial parasites, the various agglutination reactions for enteric and Alcaligenes groups all were negative. The one definite thing is that he tends to get worse when not taking liver in some form. Even with active liver treatment his red blood count is only about 3,400,000 per cubic millimeter. It is unlikely that the condition is one of the so-called eosinophil leukemias, as the total leukocyte count is relatively low. The author regards this case as one of pernicious anemia with an extraordinarily high eosinophil count.

Mixed Tumor of the Face—Ray describes a mixed tumor of the face unconnected with the parotid gland, the greater part of which was composed of a large single translucent cyst containing a clear yellow fluid. Basal cells were present and some of the smaller cysts were lined by basal cells. It is known that the mixed tumor may take the form of a basal cell tumor or of adenoid cystic epithelioma. But when the cell masses are more compact, the cells tend to assume a somewhat irregular form. Histologically, the tumor has to be differentiated from endothelioma. Every unusual tumor that lacks easily recognizable characters stands an excellent chance of being labeled endothelioma. Further, atypical endothelioma can scarcely be regarded as having an established position. In the author's case there was a tendency to cylinder formation, but it is a peculiarity seen in other tumors besides cylindroma. The diagnosis of atypical endothelioma is admittedly difficult. Kettle has laid down the rule that the negative properties of a cell cannot demonstrate its origin, and it is only when the cells of a neoplasm present positive evidence of their endothelial nature that one is justified in calling the tumor an endothelioma. The formation of the cystic spaces is due to degeneration of the stroma or they are the result of desquamation or of the secretory activity of the cells of the neoplasm. There is no doubt that the varied natures of the component cells and the supporting stroma are readily explained, if the tumor is regarded as an "enchymoma" of embryonic origin. The new growth was therefore diagnosed as a mixed tumor of the parotid region, of the extraglandular variety.

*Maneuver for Correcting Posterior Parietal Presentation of the Child so as to Permit of Successful Delivery with Forceps R A Lemme—p. 859

Treatment of Uterine Hemorrhage—Epps treated 141 patients for excessive uterine hemorrhage with radium. In the majority of instances the hemorrhage was not due to any demonstrable lesion, and in no case due to cancer. With the patient under anesthesia the length of the uterine cavity was measured by a graduated sound, and a dilation and diagnostic curettage were performed. Either 50 mg or 30 mg of radon

in a small uterus, screened by 1 mm of platinum and 15 mm of rubber, was inserted into the uterus. The rubber tube, which had been cut to correspond with the uterine length, was stitched so that an empty cuff remained in the cervical canal, the radium occupying only the uterine body. The vagina was packed with gauze wrung out in 1 2,000 solution of acriflavine hydrochloride in physiologic solution of sodium chloride. The dosage was adjusted by the length of time the radium was in place. Complications did not follow the use of radium in this series, and the patients were discharged from five to seven days after treatment, unless they were anemic. For the treatment of menopausal hemorrhage, radium is practically a specific. From this series the author concluded that a dose of 1,100 millicurie hours is satisfactory and should rarely be exceeded. In younger women, cancer being excluded, a longer trial of medical treatment should be given. Should this fail, radium is indicated before hysterectomy is considered. The minimum effective dose is advisable, in order to avoid the possibility of a premature climacteric or, if pregnancy should follow, complications of labor. Such a dose is probably 300 millicurie hours during adolescence and from 500 to 700 millicurie hours during the child bearing age. If attention is paid to the details of the technic, stenosis of the cervix and the upper part of the vagina should not occur. Sufficient time (up to six months) should elapse after treatment before its efficacy can be judged. If the condition of the patient is grave, an earlier second dose may be necessary. The use of small doses should avoid the appearance of menopausal symptoms in the young or their accentuation in the older woman. A small dose, repeated if necessary, is preferable to overdosage. Seventeen cases of uterine hemorrhage were associated with fibroids, which were small and for the most part discovered only after examination under anesthesia, a dose of from 1,100 to 1 200 millicurie hours was satisfactory in fifteen cases.

Correcting Posterior Parietal Presentation of Child—Lemue believes that a corrected posterior parietal presentation can be maintained in its new position if the fundus of the uterus is drawn upward and forward by abdominal manipulation. By this means the body of the child is brought away from the maternal spine, thereby correcting the obtuse angle between the body and head of the child. The maneuver consists of altering the posterior parietal position into that of an anterior parietal, by pushing the sagittal suture, facilitated by a fold of the scarp, backward toward the sacral promontory. When this is accomplished the head is steadied in its corrected position, while an assistant passes his hands deeply behind the fundus and raises the uterus upward and forward. Forceps are then applied without the retaining hand being removed from the vagina, and delivery is often successfully accomplished after previous attempts with the forceps have failed. By this maneuver delivery of a live child has been made possible on many occasions when previous attempts at delivery by forceps had failed and craniotomy was advocated as the only possible line of treatment. The maneuver can be demonstrated in the living subject before delivery. When the position of the head has been corrected, it will be noted that the act of raising the fundus upward fixes the head firmly in its new position.

Bilious Migraine—Hunt analyzes sixty cases of migraine forty of which were of the bilious type. Investigation by biliary drainage and oral cholecystography showed some evidence of gallbladder or hepatic disorder in seventeen of twenty-seven selected bilious cases. A higher proportion of migraine patients as a whole show evidence of gallbladder disorder than normal subjects. Evidence of stasis in the gallbladder was

found in seven of twenty-seven patients examined by biliary drainage. Local gallbladder disease or dysfunction is not a cause of migraine but may occur as the result of repeated migraine attacks or of some primary underlying hepatic or constitutional cause. Cholecystectomy had no effect in relieving migraine attacks in five of six patients. The author emphasizes the importance of inquiry for migraine attacks in subjects of gallbladder disease and its bearing on the results of cholecystectomy. He records the results of treatment by bile salt preparations by mouth in twenty-two selected patients nineteen of whom were improved, and suggests that some hepatic dysfunction may be a cause of migraine attacks in certain cases, this is supported by the results of bile salt treatment. Epinephrine given subcutaneously is capable of aborting migraine attacks in a high proportion of cases. The usual dose has been 10 minims (0.6 cc.) of the 1 1,000 solution, but 15 or 20 minims (1 or 1.3 cc.) has sometimes been given in which case it was injected slowly. Of fourteen attacks (nine patients treated), ten have been completely aborted three definitely ameliorated and one unaffected. The later the injection is given the larger it should be but the less effective is its action. Although migraine is regarded as allergic in origin, perhaps akin to a cerebral angioneurotic edema little mention appears of the use of epinephrine in its treatment. The fact that in certain cases it is capable of checking the migraine attack suggests that some vasodilatation rather than a vasoconstriction of the cerebral vessels may be at fault, though any direct effect of epinephrine on these vessels is uncertain, and of course the possibility of suggestion cannot entirely be excluded. The few opportunities that the author has had of treating the actual attacks with epinephrine make him feel that its effect may be as beneficial as in asthma, provided a sufficient dosage is employed.

Treatment of Asthma—Todd recommends that, in the routine treatment of asthma, errors of diet, dentition and bedroom hygiene should be corrected. Continued sensitization of the bronchial mucosa from the ethmoid zone should be prevented by conservative surgery if necessary and the ethmoid pack should be repeated periodically. The antiallergen should be desensitized or saturated by prolonged parenteral injection of the fecal vaccine. A small dose of thyroid extract should be administered daily. The patient should be permitted to have caffeine with the addition of ephedrine to take at the first sign of an asthmatic attack. Alkalosis, hypocalcemia and vagotonia should be corrected by the prolonged administration of a mixture of calcium chloride, to which the appropriate dose of tincture of belladonna has been added.

Chronic Colibacillæmia—Desgeorges states that hemic infection of the gallbladder with *Bacillus coli* derived from the intestine is the chief factor in the causation of cholelithiasis. Colon bacilli in the blood are eliminated in both the urine and the bile. Colibacillæmia invariably reacts on the liver and bile ducts causes hypercholesterolemia and, from its frequency, is one of the chief causes of this condition. Most patients with gallstones have or have had colibacilluria and most of the subjects of chronic colibacillæmia eventually suffer from cholecistitis and biliary lithiasis. The best available prophylactic

measure as regards cholelithiasis is to prevent the passage of the colon bacillus from the intestine into the circulation and is one of the first steps to be taken in the treatment. The hypothesis of colibacillemia of intestinal origin throws light on the whole subject of biliary lithiasis and explains the chief clinical and experimental data underlying previous hypotheses of the pathogenesis of this disease.

*Avoiding Postoperative Accidents Accompanied by Hyperazotemia and Hyperchloremia M. Robineau and M. Levy—p. 1563
Antidiphtheric Serum Therapy R. A. Marquez, A. Bourdin and Mlle D. Ronget—p. 1568

Postoperative Accidents Accompanied by Hyperchloremia—Robineau and Levy recommend the prophylactic injection of hypertonic salt solution for the prevention of the postoperative accidents accompanied by hyperazotemia and hyperchloremia. All operations result in disturbances of the organism manifested by various degrees of hyperazotemia with hyperchloremia, oliguria, elaboration of large quantities of urea from the nitrogen contained in the tissues (which may remain in the blood or be eliminated in the urine), reduced elimination of chlorine and sometimes functional nephritis from loss of the power of concentrating urea. None of these serologic manifestations are individually responsible for the early or late postoperative accidents, some may be missing and their reciprocal relations are not clear, but these organic disturbances may certainly be considered responsible for the occurrence within from twenty-four to forty-eight hours after operation of an intestinal paralysis with a syndrome of occlusion and general symptoms of toxemia. They must also be considered responsible for the late accidents of the same nature appearing from eight to twelve days after the operation with general weakness, loss of weight and loss of muscular strength. Intravenous injections of hypertonic salt solution are not always efficacious in these grave postoperative accidents but if administered from the moment the operation is terminated they combat the disturbances produced in the organism. The amount of urea and chlorine in the blood remain practically normal, the rest nitrogen is lowered, uremia is nearly normal, the output of urea in the urine is not increased and the output of chlorine is not decreased. Clinically, this prophylactic treatment results in a disappearance of malaise after awaking from the anesthetic, a rapidly manifest state of well being, regularity of the pulse, moisture of the mouth, absence of thirst, decrease of vomiting (if it exists), early emission of gases after abdominal operation, and absence of fatigue. The loss of weight and strength is greatly attenuated. Above all, the prophylactic injection of salt protects the patient against all grave accidents not directly due to the act of operation.

Organization of Proprioceptive Centers of Medullobulbopontomesencephalic Axis J. Nicolesco—p. 361

*First Cerebellar Signs in Tumors of Cerebellopontile Angle Heterolateral Cerebellar Syndrome K. Henner—p. 377

Tumors of Cerebellopontile Angle—Henner states that tumors of the cerebellopontile angle, before the classic cerebellar syndrome is fully manifest, give rise to the well known symptoms of cerebellar deficiency and also to their opposites. Thus, instead of hypermetria hypometria may be observed and in the prehension test the patient may not open his hand immoderately but keep it more closed during the movement itself than would a normal person. The author considers these symptoms the result of cerebellar irritation or hyperfunction and likens them to Parkinson's syndrome, which he regards as a syndrome of cerebellar hyperfunction, the reverse of the classic cerebellar syndrome. Some symptoms of cerebellar hyperfunction or parkinsonian elements are found in practically every cerebellar syndrome. The author has observed the reverse cerebellar syndrome in ten cases of tumor of the cerebellopontile angle (seven verified, three clinically certain). On the basis of these he describes the topography and order of appearance of the reverse cerebellar symptoms or parkinsonian elements in

tumors of the cerebellopontile angle. At first one sees simultaneously with classic cerebellar symptoms certain parkinsonian elements, such as decrease of the pendular movements during walking, circumscribed plasticity in some segment of the extremities, and increase of the elementary posture reflexes, to which, perhaps, belongs the intention tremor (which sometimes diminishes in the later stages). Later, axial symptoms of the vermis appear, here it is difficult to separate the vestibular symptoms from the symptoms of cerebellar irritation, in view of the fact that the gray nuclei of the vermis are counted in the central vestibular system. In this stage heterolateral symptoms of cerebellar hyperfunction can be observed (localized plasticity, increased elementary posture reflexes, and so on). Homolaterally the hyperfunctional cerebellar symptoms disappear rather rapidly, but they persist longer and are more frequent on the heterolateral side. Later classic symptoms of cerebellar deficiency also appear heterolaterally. Finally in advanced stages or after trepanation all the reverse cerebellar symptoms disappear and the classic cerebellar syndrome more pronounced on the homolateral side is manifest. While this description of the reverse cerebellar symptoms is schematic, a certain regularity in the order of the symptoms can be observed if one looks for the parkinsonian as well as the classic cerebellar symptoms and for both on the two sides. This regularity is not observed in intracerebellar tumors which gives the syndrome a practical value in doubtful cases.

*New Species of Salmonella Genus L. Salles Gomes—p. 167
Blood Eosinophilia in Parasitic Infestations S. B. Pessoa and J. Alves Meira—p. 175

New Species of Salmonella Genus—Salles Gomes isolated four organisms of the Salmonella genus, one from the mucopurulent and bloody feces of a patient in the initial period of a dysenteriform syndrome, one from a specimen of purulent urine and two from the blood of two patients at the peak of a paratyphoid like infection which proved to be fatal. The agglutination test which was performed with only one of the blood specimens, gave strongly positive results. The four organisms proved to have identical characteristics as to morphology, motility, stain and culture reactions and biochemical properties related to their reactions in twenty-one carbohydrates, indole, nitrates, sulphurated and acetyl-methyl carbinol. They caused gas fermentation with salicin did not produce indole and were pathogenic to laboratory animals. The emulsion of cultures of the isolated bacteria killed mice and guinea pigs in from twenty to twenty-four hours after injection into the peritoneal cavity. The intravenous injection of the emulsion produced death in rabbits in from thirty-two to seventy-two hours. Nevertheless mice receiving the emulsion by mouth did not die. With the aid of Castellani's tests, the author studied the serologic relations between the strains and their corresponding antiscrums. He did not find any correlation between the anti-serums of his organisms and Salmonella supester (Voldagen, Newport, Reiding and Stanley), typhimurium, aertrycke, paratyphi schottmulleri and enteritidis. He believes that the organism is a new species of the Salmonella genus and proposes to name it Salmonella pauloensis, since it was isolated from material of patients who were permanent residents of São Paulo.

*Chloroform in Treatment of Bronchospirochetosis R. Denis, F. J. Bares and J. D. Araoz—p. 2005

Pulmonary Syndrome in Mediastinal Polyadenopathy—Spangenberg and Rossi Belgrano state that the compression of some mediastinal organs is usually caused by the presence of tumors and aneurysms in the mediastinum. Roentgen examination of patients presenting clinical symptoms of compression of the mediastinal organs is important since it may reveal the presence of hypertrophic ganglions as the cause of the compression. The authors' patient, aged 50, presented a pulmonary

syndrome with nonproductive reflex cough paroxysmal dyspnea and, on auscultation, the presence of respiratory and bronchial murmurs similar to those heard in pneumonia. The clinical picture indicated an acute attack of bilateral pulmonary disease. Nevertheless, there was no fever and the symptoms were of a stationary nature. The roentgen examination showed that the areas of apparent dullness according to the auscultation were clear and that the respiratory murmurs, the bilateral congestion of the lungs and the presence of hydrothorax and of paroxysmal dyspnea were caused by compression of the bronchi the pulmonary veins and the sympathetic and pneumogastric nerves, respectively, by hypertrophic ganglions due to chronic mediastinal polyadenopathy of the patient.

Chloroform in Treatment of Bronchospirochetosis.—Dennis and his collaborators report the case of a man who had had apparently cured syphilis in his youth. At examination during his present illness the patient presented bronchospirochetosis, complicated by syphilitic gummatous laryngitis. The patient received six treatments with chloroform inhalations, which were given at intervals of from twenty-five to thirty minutes. The chloroform treatments were given in doses of 5 Gm each except the first in which the patient received 10 Gm. The treatments were given at three day intervals, except the second and third, which were given ten days apart on account of the intense laryngeal shock that the patient presented while taking the first inhalations during the second treatment. The ultramicroscopic examination of the sputum after the last treatment showed complete absence of spirochetes which still persists five months after the end of the treatment. The syphilitic gummatous laryngitis was completely cured by the administration of bismuth compounds.

Active Immunization Against Chickenpox.—Von Gulacsy reports his experiences with active immunization against chickenpox in the course of an epidemic in a children's clinic. Vaccination was done in most cases by intracutaneous injection. Only in five cases was scarification done according to Kling's method. The fresh vesicular contents were collected in sterile capillary tubes diluted 1:10 with an isotonic solution of sodium chloride and injected into the skin. All children who were not vaccinated developed chickenpox, while of those who were vaccinated only 13 per cent contracted the disease in an abortive form. Thus it can be said that the vaccination has excellent protective value. The development of the immunity is not dependent on local reactions. Circumscribed reddishness and light infiltration were present in only a few cases and were probably the result of mechanical irritation. Studies of the blood pictures disclosed that the vaccination produces the same changes as does the disease.

Sugar Therapy in Nephritides.—Von Bokay and von Kostyal treated acute nephritis with an exclusive sugar diet for a number of days usually until improvement sets in the patients are given from 250 to 400 Gm of malt sugar or potato sugar and nothing else. After that some fruit and a little water are added and gradually a mixed diet is again introduced. The authors employed this treatment in fifty cases. Acute hemorrhagic glomerular nephritis was found in thirty-four of the patients, 10 had subacute hemorrhagic nephritis, five chronic nephritis, six nephrosis and one a scarlet fever nephritis.

complicated by erysipelas and sepsis. This patient died on the day following hospitalization. The patients with acute nephritis recovered in fifteen days or less and those with chronic nephritis or nephrosis recovered in from fifteen to thirty days. The exclusive sugar diet rests the kidneys and thus promotes the recovery. The favorable effect of the sugar diet is partly the results of a direct action on the intermediate metabolism and partly of an indirect action by way of the liver. The sugar diet also influences the disturbed water exchange that exists in renal inflammations. It reduces the oncotic pressure of the blood and tissues, increases perspiration and reestablishes the renal and extrarenal elimination of water.

Allergy Theory of Chickenpox in Case of Encephalitis.—Mayerhofer and Breitenfeld report the history of a boy, aged 14 who nineteen days after the first appearance of chickenpox (that is, within the period of the appearance of allergic reactions) developed encephalitis with hydrocephalus followed by bilateral choked disk of 6 and 55 diopters and complete loss of vision. The chickenpox that preceded the encephalitis was extraordinarily severe (confluent varicella with variola-like scars). The epidemic in the patient's home town was mild and particularly the person who had infected this patient had a rather mild form of chickenpox. Smallpox could be excluded epidemiologically as well by the fact that the patient had been vaccinated during the first year of life and again when admitted to school (presence of four large vaccination scars). The deleterious results of the bilateral choked disk could be counteracted neither by lumbar puncture nor by the simple puncture of the corpus callosum. The choked disk did not disappear until after Forster's operation had been done. After that vision was gradually restored, until after eight months it had become completely normal again. The authors assert that the literature contains no other report of encephalitis due to chickenpox with such a severe form of choked disk. In the etiologic interpretation of this encephalitis they accept Glanzmann's allergic theory. They base this assumption on the development of the second disease nineteen days after the first appearance of the eruption and also on the fact that the patient retained a hypersusceptibility to the smallest quantities of iodine, owing to sensitization of the brain in the course of the operation. Minute doses of iodine elicited epileptic spasms of the Jacksonian type.

New Pneumothorax Needle F Hochstetter—p 1470

Complement Fixation in Tuberculosis During Childhood.—In testing the reliability of the Leuchtenberger-Lorenz complement fixation reaction, Joppich found that although the reaction frequently gives positive results in active tuberculosis in children, it does so also in apparently inactive cases. Consequently it cannot be used in the differentiation of active and inactive tuberculosis. To be sure, the objection may be made that the 'inactive' cases have been wrongly estimated, that namely an active process was present but could not be detected with the available methods. But to this objection the reply may be made that the reaction was also positive in a considerable number of children who were not infected with tuberculosis which proves that the reaction is not sufficiently specific and consequently is not suitable for diagnosis in pediatric practice. The author recommends that in all complement fixation tests for tuberculosis the specificity be tested first by performing the test on serums from children who are known to be free from tuberculosis.

Sources of Error in Demonstration of Tubercle Bacilli in Blood.—Loewenstein admits that his method of demonstrating tubercle bacillema is difficult but he thinks that if certain

errors in the technic are avoided, the negative results reported by many investigators, even in severe cases of tuberculosis, will diminish and the importance of the blood culture will be realized. In acute articular rheumatism, in which so many investigators obtained negative results, it is important to withdraw the blood during the increase in fever and before treatment with salicylic acid has begun. The earlier stages of a disorder are, as a rule, better suited for the blood culture than the later stages. In tuberculosis, for instance, the blood culture may be positive at a time when the roentgenogram is still negative. The author emphasizes that during the withdrawal of the blood no disinfectant should be used, such as corrosive mercuric chloride or iodine. The walls of the tube in which the blood is withdrawn should be moistened with a 10 per cent solution of citrate. Immediately after the withdrawal the blood should be well shaken so as to prevent coagulation, for once the tubercle bacilli have been enclosed in the clot of fibrin they cannot be liberated again in the living state. The complete removal of the hemoglobin is another important factor. The culture medium should not be older than ten days and, in preparing it, care should be taken that during the coagulation the temperature does not exceed 85 C. Sterilization should be done in the steam sterilizer never in a dry sterilizer. After the culture medium has been inoculated, the tubes should be closed air tight by means of sealing wax, because the smallest air hole will lead within three weeks to drying out and hardening of the culture medium. The author maintains that with his method tubercle bacilli can be demonstrated not only in the various forms of tuberculosis (lungs, eyes, bones, skin and intestine) but also in other disorders, such as rheumatism, polyarthritis and dementia praecox.

Physiology of Fracture Healing—According to Timpe, Robinson demonstrated the existence of phosphatases, principally in the cartilage and to a lesser degree in the various organs and tissues of young animals, which play an important part in the ossification of bones. These phosphatases are split off from the hexose diphosphoric and glycerophosphoric acids. Timpe found that these phosphatases are likewise present in the muscles and cartilage of adults under normal conditions. He further showed that there exists in the human organism in the course of healing of a fracture a third phosphatase, which splits phosphoric acid from nucleic acid. The role of this phosphatase in the healing process is just as important as that of the other two phosphatases. It was present in the callus, in the bones at the seat of the fracture, and in the muscles in the vicinity of the fracture. Its production in the muscles appears to be due to the formation and absorption of the hematoma in the muscle. The author considers the breaking down of cells the cause of the appearance of this phosphatase in the muscle, because the nucleic acid splitting phosphatase is found not only when a fracture exists but also as a result of postmortem changes.

Healing of Fractures and Carbohydrate Metabolism—Timpe and Reich state that urinalysis at regular intervals in several hundreds of patients presenting healing fractures demonstrated glycosuria in only one instance. This was of a short duration and accompanied by a mild hyperglycemia. Determinations of blood sugar in nineteen of the patients demonstrated hyperglycemia in two instances (10 per cent). Hyperglycemia was present in eight out of twenty-three cases of injury to the

skull (35 per cent). In concussion of the brain, hyperglycemia was found with equal frequency regardless of the existence of a fracture of the skull. The hyperglycemia developed shortly after the injury and persisted for a brief period only. A persistent rise of blood sugar was not observed. A traumatic diabetes probably does not occur. The transient traumatic glycosuria as well as hyperglycemia is apparently of a central nervous origin. In concussion of the brain the effect on the metabolic centers is a direct one, and in fractures of the extremities an indirect one. Stimuli proceed along sympathetic paths from the seat of fracture to the centers, which in their turn send out efferent impulses to the organs that control the carbohydrate metabolism and the liver, kidneys, suprarenals and pancreas.

Iron Medication and the Intestinal Flora—Lotze reports experimental bacteriologic investigations on the action mechanism of high doses of iron. The experiments disclosed that high doses of iron have a bactericidal action on the aerobic as well as on the anaerobic intestinal flora. From this he concludes that the former opinion about the action mechanism of iron has to be extended, for its value lies not only in its direct influence on the synthesis of hemoglobin but also in its action on the intestinal flora. Whether this explanation applies only to the anemias that develop in grave colitis, in sprue or following the exclusion of larger portions of the intestine, or whether it applies also to anemias of different origins will require further investigations.

Thrombosis of Splenic Vein—Lichtenstein and Plenge discuss the differential diagnosis of chronic tumors of the spleen in hematopoietic and in hepatolienal disturbances and the confused nomenclature of splenomegaly, splenic anemia, Banti's disease and pseudo-Banti's disease. A case of their own observation presented the symptomatology of thrombosis of the splenic vein, while its anatomic examination disclosed a pronounced proliferation in the splenic pulp, reticulum and connective tissue, without involvement of the splenic vessels. On the basis of thirty-two cases reported in the literature, the authors outline the syndrome of thrombosis of the splenic vein and call attention to a group of cases in which, although the symptomatology is the same, thrombotic changes in the walls of the splenic vessels are absent. Thus the symptomatology of thrombosis of the splenic vein includes disturbances of various origins, and there is really only a syndrome of thrombosis of the splenic vein, not a disease entity. The authors attempt a classification of the cases of thrombosis of the splenic vein on the basis of the anatomic aspects. They differentiate true thrombosis of the splenic vein, true thrombosis of the splenic and portal veins, and chronic inflammatory (?) splenic tumor without involvement of the splenic vessels.

Chloride-Free Diet and Withdrawal of Gastric Juice in Treatment of Ulcer—In the treatment of fifty-five patients having ulcer and of fifteen patients having gastritis, Katsch and Mellinghoff employed a 'salt-free' diet. The foods were selected and the sodium chloride was restricted in such a manner that the daily intake of sodium chloride did not exceed 12 Gm. In addition to this, gastric juice was withdrawn by means of a permanent catheter, at first daily and later at intervals, and in

order to reduce the sodium chloride still further, salyrgan was injected to stimulate diuresis and chloride elimination. The effect was favorable and lasting improvement could be observed. The improvement was most noticeable in patients presenting hypersecretion, and even cases that had been refractory to the usual therapeutic procedures quite frequently yielded to this treatment. The hypersecretory and the refractory cases are the primary indication for the treatment, but in pyloric stenosis with persistent vomiting and in hypochloremia the treatment is contraindicated. There is a considerable loss of sodium chloride from the tissues, and the gastric secretion is reduced primarily as regards the quantity of juice but less as regards the acid concentration and the total chloride content.

Migrating Phlebitis—Buschke and Joseph review the literature and report a case. Resection of thrombosed veins and injections with a circulatory hormone preparation proved unsuccessful. They resorted to injections of mercury and later combined this treatment with the administration of an iodine solution. The injections of mercury were made daily with 3 Gm of the ointment. After three weeks a considerable improvement was noticeable and after two months the phlebitic changes had largely disappeared and the pain had entirely subsided. An examination after six months revealed that the favorable effects had persisted. The authors think that the good results were primarily achieved by the mercury but admit that the iodine may have helped. They consider this success the more noteworthy since all former therapeutic measures failed to bring the desired results, largely owing to the fact that a causal therapy has been impossible, because the cause of migrating phlebitis is not completely understood as yet. They consider most probable the presence of a latent infection which flares up through external influences of a traumatic or chemical nature. The occurrence of similar venous disturbances on a syphilitic and tuberculous basis seems to corroborate this theory. In some cases of migrating phlebitis the anamnesis discloses previous acute infectious diseases, such as typhoid and influenza. Other authorities assume a focal infection in the oral cavity while one assumes a toxic or infectious disturbance of the sympathetic nervous system which in turn causes angiospastic manifestations with circulatory disturbances and impairment of the vascular walls. The authors consider the latter theory more likely than that of an allergic origin.

Epinephrine Secretion in Insulin Hypoglycemia—Kugelmann gained the impression that the hypoglycemic symptoms: palpitation of the heart, tremor, pallor and feeling of pressure over the sternum are not the direct result of the action of insulin but are caused by an increased secretion of epinephrine. He reasoned that if this theory was correct it should be possible to produce by the simultaneous administration of ergotamine tartrate and insulin a hypoglycemic condition in which the epinephrine symptoms would be absent as it is known that ergotamine tartrate checks the effects of epinephrine. By the simultaneous administration of insulin and ergotamine tartrate he succeeded in producing in four out of ten patients a hypoglycemic condition in which involvement of the vascular and

circulatory apparatus was absent. This proves that the hypoglycemic condition consists of two components, a direct insulin action and a regulatory epinephrine action. In Pal's vascular crises, during increase of blood pressure the author observed hyperglycemia, hyperleukocytosis and lymphocytosis, conditions that can be explained by an endogenic epinephrine elimination.

Babinski's Reflex—According to Marburg, the reflexogenic zone of the Babinski reflex is quite extensive. Babinski first elicited it by stimulating the medial edge of the soles of the feet. Later, reports appeared about the elicibility from the external edge from the balls of the toes from the Achilles tendon, by stroking the crest of the tibia or by lifting the toes and suddenly releasing them and by bending the knee against the resistance of the pressure of the hand. However, knowledge on the connection between the various means of eliciting the reflex and the pathologic-anatomic changes is still deficient, for Goldflam's attempt to employ Rossolima's modification for the differential diagnosis of multiple sclerosis did not prove reliable. The author points out that Edelmann proved in 1920 that Babinski's sign could be elicited in cases in which Kernig's sign is positive, particularly when meningitis or cerebral edema exists. Edelmann could show that in cases of meningitis, when the leg with extended knee is bent at the hip joint, a dorsal flexion of the great toe is frequently observed although Kernig's sign may be negative. This symptom may become positive in an early stage, particularly in senile meningitis, in which rigidity of the neck and Kernig's sign may be absent. Moreover, the symptom also occurs in cerebral edema. In meningitis it disappears toward the end but in cerebral edema it persists until death. The author watched for this symptom and his observations corroborate Edelmann's report. He also made anatomic studies in two cases in which the symptom had persisted until death. These two patients had had hypertension and the histologic examination disclosed severe edema of the brain and the meninges. Two patients with cerebral tumor who had a meningitic symptomatology, likewise presented the symptom. The histologic examination revealed no signs of meningitis but disclosed edematous conditions. Since it has been assumed that the Babinski reflex is indicative of impairment of the pyramidal tract the author examined the pyramidal tracts histologically but they proved intact in the patients with cerebral edema. Thus Edelmann's symptom is indicative of meningitis or of meningeal or cerebral edema. It should be remembered that the symptom may appear without Kernig's sign and that in edema it persists until death while it may disappear in meningitis. Moreover the development of this sign is not dependent on the presence of a lesion of the pyramidal tract. A lesion of the cerebral cortex or of the meninges is apparently sufficient for its appearance.

Baths with Irradiated Salt Solutions—Szerdotz shows that by the use of irradiated salt solutions a new principle has been introduced into balneotherapy. A solution of a mixture of potassium salts is irradiated for seven minutes with red light and then for fifteen minutes with the quartz lamp. One liter of this solution is then added to the bath which has a temperature of 36°C (96.8°F). The bath lasts twenty minutes and

following it, the patient rests from one-half to one hour. The first few baths usually produce a decided euphoria, but after seven or eight baths the pains often become severe again. If the reactions are too severe, the treatment should be interrupted for several days. However, after twenty baths have been given there is usually a decided improvement. The author employed the baths in the various forms of arthritis and in neuritis, myalgias and rheumatoids, with favorable results. He ascribes the efficacy of the baths to actinic energies of the irradiated salts. He thinks that certain micro rays, perhaps beta rays, are liberated in the bath and exert an activating influence on the various functions.

Simple Staining Method for Blood Preparations.—Although the panoptic method of blood staining devised by Pappenheim gives excellent results, Gutstein made efforts to find a new one that would be less complicated and more rapid so that it could be used by the practitioner during consultation. The stain prepared by him contains methylthionine chloride 2 B, thionine and acid eosin dissolved in methyl alcohol. The first preparation of the stain is somewhat complicated, but it can be kept in readiness for quick use. The prepared stain is dropped on the blood smear. After three minutes the fixation is complete and distilled water is added so as to distribute the stain evenly. Rinsing with distilled water is followed by drying with filter paper. The nuclei of the lymphocytes and monocytes show a dark violet stain, while the protoplasm appears grayish blue. The nuclei of the neutrophil leukocytes are distinctly violet and differentiation between segmented nuclei and rod-shaped nuclei is easy. The protoplasm of the neutrophils contains fine pinkish to rose-violet granules. The eosinophils show large red granules and a violet nucleus. The mast cells have large, dark violet or red-violet granules and the nuclear stain is usually indistinct. The blood platelets appear as pale bluish-violet bodies. The author states that his staining method somewhat modified can be used also for a prolonged staining of blood smears, and he is convinced that in this case it is not inferior to Pappenheim's panoptic method.

Circulation and Respiration in Tuberculosis.—Cobet differentiates between circulatory disturbances caused by toxic factors and those due to mechanical influences. He emphasizes that acute toxic circulatory disturbances do not contraindicate collapse therapy of pulmonary tuberculosis but indicate it when the toxin resorption can be checked by the collapse therapy. Chronic toxic circulatory disturbances due to toxic impairment of the myocardium contraindicate collapse therapy only when they are especially severe, which has to be determined by functional tests. In this connection the electrocardiogram and the work test are of especial value. In discussing the mechanical influences of tuberculosis on the circulatory organs, the author mentions especially those caused by the displacement of the heart and of the large vessels and those produced by the inhibition of the respiration, particularly by shrinking. He describes the symptomatology, the electrocardiographic aspects and the respiratory conditions in these disturbances and shows that the impairment of the pulmonary function can be determined on the oxygen deficiency of the arterial blood or on the rapidity of the circulation. In patients with manifest pulmonary insufficiency, collapse therapy is as a rule inadvisable. The author considers Kauffmann's water test unsuitable for the determination of the circulatory function of patients with pulmonary tuberculosis. He discusses the circulatory disturbances produced by collapse therapy. He maintains that partial pneumothorax in

which the heart is hindered by adhesions, is most frequently the cause of circulatory disturbances, but that phrenic exeresis also may lead to impairment of the circulatory function. He states that not every one who wishes to resort to collapse therapy has to perform all the complicated tests described by him, for the final decision should be based on the clinical observation. He emphasizes, however, that the tests sharpen the diagnostician's eye.

Behavior of Blood Pressure in Oxygen Inhalation.

Studies by other investigators on the relations between hypertension and dyspnea induced Voit and Cyba to investigate the influence of hyperventilation and of oxygen inhalation on persons with normal, high and low blood pressures. It was found that under the influence of hyperventilation only some of the persons with normal blood pressure show a slight decrease in pressure while persons with hypertension regularly show a small and temporary decrease in blood pressure. The influence of oxygen inhalation on the blood pressure was less noticeable and less regular in that only some of the patients with essential hypertension reacted with a slight decrease. Thus the experiments indicate that stimuli to which persons with normal pressure react only slightly or not at all elicit as a rule a noticeable reaction in patients having hypertension. This proves the abnormal reactivity of the vascular apparatus in essential hypertension. Persons with hypotension, on the other hand, are completely refractory to the stimuli. Carbon dioxide inhalation produces in all three groups a noticeable increase in blood pressure. In this case the stimulus is evidently so strong that even the persons with hypotension react to it.

- *Prognosis in Intrathoracic Tuberculosis in Childhood C. J. Lundquist —p 161
- Possible Method in Treatment of Hemophilia? H. von Samson-Himmelstjerna —p 231

Prognosis in Tuberculosis in Childhood.—In his after examination in 926 cases of children up to the age of 15 years treated in the Stockholm hospital for tuberculosis from 1910 to 1920, Lundquist found that about one fourth of all the children died from tuberculosis, three fourths of the deaths occurring in the first five years after infection. The mortality curve showed two peaks, one for children infected in the first years of life and a lower peak for those infected at puberty. The prognosis was best for children between the ages of 3 and 6. Of the 671 surviving out of the 926 78.2 per cent were well or without signs of active pulmonary tuberculosis on examination after discharge. In tuberculosis of the bronchial glands and in cases showing massive parenchymal indurations the prognosis was favorable but less favorable in cases showing roentgenologically demonstrable disseminated parenchymal indurations. In cases in which there were large cloudy shadows with indefinite contour the prognosis was grave about half of the patients had open tuberculosis and 62.9 per cent died from tuberculosis mostly within one year after admission. Of children not roentgenologically examined but having probable parenchymal lesions 20 per cent died from tuberculosis. The prognosis was especially grave in cases presenting constant hard rales and bronchial respiration. 40 per cent of these patients had open tuberculosis and 87.2 per cent died from tuberculosis, more than one half within half a year and more than 70 per cent within one year after admission. Of tuberculin positive children not having certain clinical or roentgenologic changes, 16.4 per cent died from tuberculosis. In open tuberculosis the prognosis was extremely grave with a mortality of 86.9 per cent, 60 per cent of the children dying within the first year and 86.3 per cent within the first three years after demonstration of tubercle bacilli in the sputum, 84.5 per cent of these patients were approaching or at the age of puberty, and there were twice as many girls as boys. Of the eight children who had open tuberculosis and were given pneumothorax treatment, three were alive. Whooping cough and scarlet fever had no noticeable effect on the tuberculous process measles usually caused a transient aggravation, and epidemic influenza produced in some cases a flare up or an aggravation with fatal outcome and in most cases no aggravation or only a temporary aggravation.

DIETARY AND MEDICAL MANAGE- MENT OF DISEASES OF THE GALLBLADDER

NEWER POINTS OF VIEW

JOHN RUSSELL TWISS, M.D.

AND

CARL H. GREENE, M.D.

NEW YORK

Progress in any field of medicine is not a uniform process. The introduction of new points of view for the study of the disease process, the developments of new technical methods of examination, or advances in any of the medical sciences may lead to renewed interest, intensive study and rapid progress, at least for a time. The last decade has seen such an interest in the anatomy, physiology, chemistry and pathology of the liver and biliary tract.¹

It is desirable at the present time, therefore, critically to review this literature and to point out the application of these newer points of view in improving the therapeutic management of the patient with disease of the liver or biliary tract.

Mann² has reported, in summarizing both the literature and his own studies, that he has come to consider the gallbladder as a part of a mechanism whereby the secretory activity of the liver is correlated with that of the gastro-intestinal tract. In the fasting state preceding a meal, the liver is active but the amount of bile secreted is relatively small. The gallbladder is partially filled with concentrated bile, of which the bile salts are a most important constituent. The sphincter at the end of the common duct allows amounts of bile to escape into the duodenum only at infrequent intervals and most of the bile secreted by the liver passes into the gallbladder. As soon as the ingested food passes the pylorus the chyme causes the sphincter to relax and coordinately with this the gallbladder expels a portion of its contents. The bile salts are quickly absorbed from the intestine and stimulate the liver to increased activity. With the increased secretion of bile there is an increased flow of bile to and from the gallbladder. With the stomach empty and chyme no longer

pouring over the papilla, the sphincter opens less frequently, and gradually the secretory activity of the liver is reduced to that of the fasting state. It therefore appears that the function of the gallbladder is to provide a reserve of concentrated bile which is of value both in digestion and as a means of stimulating the liver to increased activity at the time the gastro-intestinal tract is most active.

The data on which this hypothesis is based are varied and, in many particulars, still a subject for controversy. The ability of the gallbladder to concentrate the bile from several to ten fold, suggested by the work of Kemp,³ Hammarsten⁴ and Hohlweg,⁵ was conclusively proved by Rous and McMaster⁶ and by Mann and Bollman.⁷ Whether substances other than water and inorganic salts are absorbed, however, is still under debate. Examination of the gallbladder of a dog several days after the ligation of the common bile duct shows the surface lymphatics to be distended with bile-stained fluid, while two or three months later the contents of the gallbladder are reduced to a small amount of inspissated mucus that may fail entirely to give the chemical tests for unchanged bilirubin or bile acids. Mann⁴ has reported experiments indicating absorption of bile salts from the gallbladder, and Andrews and his associates¹⁰ think that such absorption and the consequent ratio of bile salts to cholesterol is an important factor in the deposition of cholesterol crystals from the bile. There would seem, on one hand, to be some evidence for assuming that the gallbladder is able to absorb bile salts from the contained bile. On the other hand, the fact that the gallbladder bile normally contains several times as much bile salts as hepatic bile suggests that such absorption usually is small in extent, at least when compared to the accompanying absorption of water.

The deposition of lipids or, more particularly, cholesterol in the mucous membrane of the gallbladder noted by Naunyn¹¹ has been termed the "strawberry gallbladder" by MacCarty¹² and, more recently, "choles-

terosis" by Mentzer¹³. The pathogenesis of this condition is now a source of acute controversy. Some investigators, as Sweet¹⁴ and Halpert¹⁵ hold that it is evidence of absorption of cholesterol from the bile by the epithelium of the gallbladder, others, as Elman and Graham¹⁶ hold to the earlier view of Naunyn¹¹ and Aschoff¹⁷ that the gallbladder secretes cholesterol into the bile. Others, as Wilkie and Doubilet,¹⁸ insist that the wall of the gallbladder behaves as a semipermeable membrane and that passage of cholesterol in or out depends on the relative concentration in the blood and bile. In any case, as emphasized by Twiss and Killian¹⁹ the concentration of cholesterol in gallbladder bile as compared to that in hepatic bile is relatively much greater than that of other biliary constituents. That the gallbladder epithelium has some secretory activity apart from the secretion of mucus, is indicated by the experiments of Mann⁴ with rose bengal.

Until recently it was a question as to whether the gallbladder ever really empties. For a long time Sweet²⁰ and Halpert¹⁵ have insisted that it never empties at all. The introduction of cholecystography by Graham and Cole¹ has done much to answer this question. When cholecystography is combined with duodenal drainage, the results in normal individuals may be dramatic. In such an experiment the patient is given the dye in the usual way. The following morning duodenal drainage is started. If successful, dilute bile (the A bile of Lyon²¹), is obtained. This bile contains little if any dye. Roentgenograms show the tip of the tube in place in the duodenum and a distended gallbladder. Stimulation by magnesium sulphate or olive oil then produces a flow of dark concentrated bile (B bile) containing much dye. This is followed by a flow of light bile (C bile) containing little dye. Roentgenograms at the end of the experiment show a marked reduction in the size of the gallbladder. While such experiments show that the gallbladder does empty, there is an extensive experimental literature which indicates that it perhaps never empties completely, and that the urinary bladder and several days may elapse before the entire content at any one particular time is removed.

Once it is accepted that the gallbladder does empty into the duodenum, the question of the mechanism involved becomes paramount. The effect of respiratory movements, changes in intra-abdominal pressure, the elasticity of the viscus, variations in the tonus of the duodenal wall or of the sphincter of Oddi, and the existence of a reciprocal innervation between the sphincter and the gallbladder²² have been discussed at length. More recently, attention has been focused on

the role of the intrinsic musculature of the gallbladder. Various observers from Doyon²³ to Potter and Mann²⁴ have noted that when the gallbladder or common duct is connected to a manometer there are small rhythmic variations in pressure that could be interpreted as due to contractions. Boyden²⁵, Whitaker,²⁶ and Higgins and Mann²⁷ have conclusively shown contractions in the gallbladder of various species from fish to guinea pigs, cats and dogs. Cholecystography furnishes at least presumptive evidence that similar contractions may occur in man. Furthermore, Ivy and his students³ have shown the presence in animals of a hormonal mechanism (cholecystokinin) which produces contraction of the gallbladder. They believe that the efficiency of such fatty substances as cream, egg yolk, olive oil and oleic acid in producing contraction and emptying of the gallbladder is to be explained by their action in stimulating the production of cholecystokinin in the mucosa of the duodenum rather than to a specific stimulatory effect of these materials either on nerve endings in the duodenum before absorption or on the wall of the gallbladder after absorption. Ivy²⁹ has also shown the effectiveness of cholecystokinin in causing emptying of the gallbladder in man.

The importance of the sphincteric mechanism at the duodenal end of the common duct as pointed out by Giordano and Mann³⁰ must not be minimized. Ivy, Voegtlin, and Greengard³¹ have recently reported experiments on a human subject in whom, after the injection of the cholecystokinin solution, gallbladder pain was produced by the contraction of the latter viscus concurrently with the development of spastic obstruction of the intramural portion of the common bile duct. In this case the intraduodenal administration of magnesium sulphate was effective in relieving the spasm and distress. Since cholecystokinin is formed after the eating of fats functional disturbances analogous to those in the subject reported by Ivy, Voegtlin and Greengard³¹ may explain some of the intolerance to fats, which is a frequent complaint of patients with chronic cholecystitis.

It is manifestly impossible at the present time to discuss, in detail, the pathologic lesions involving the biliary tract. Chronic cholecystitis with or without accompanying cholelithiasis greatly exceeds all other lesions in frequency and medical importance. The problems concerned with the cause and formation of gallstones are by no means settled. It is now recognized that the gastro-intestinal disturbances, which Moynihan³² considered the "inaugural" symptoms of

gallstones, are the symptoms of cholecystitis and have no direct connection with the presence of stones.³³ Whether gallstones are the result of an antecedent cholecystitis or by mechanical irritation are responsible for the development of a subsequent cholecystitis is not a question that can be answered at the present time. In special cases it can be shown that one or the other of these two mechanisms is presumably responsible for the troubles of the patient, but in general they can be discussed together. However, if medical therapy is ever to supplant surgery in this field of medicine it will be necessary to recognize and correct disturbances in the biliary tract before the formation of calculi.

There are various predisposing causes that must be considered in relation to the production of either cholecystitis or cholelithiasis. Particular emphasis is placed on the effects of (1) biliary stasis, (2) infection, (3) disturbances in pigment excretion, or (4) cholesterol metabolism, (5) obesity and (6) pregnancy.

Biliary stasis with stagnation of the bile in the gallbladder is important. Such stasis presumably permits greater concentration of the bile and so favors deposition of insoluble matter. It is further assumed that stasis favors the development of both infection of the bile and inflammatory processes in the wall of the gallbladder.

Infection may involve either the bile or the gallbladder, or both. Bacteriologic studies have found streptococci, which have been considered to result from focal infection arising primarily in the teeth, tonsils or appendix. Cholecystitis is a frequent complication in typhoid, and a residual infection of the biliary tract is responsible for many typhoid carriers. This is a cause of disease of the biliary tract, which we hope is of diminishing importance. These two types of infection are usually thought to be blood borne, though whether the organism reaches the gallbladder through the bile, through the cystic artery or by lymphatic extension from the liver is a source of controversy. Hurst³⁴ believes that the majority of cases of cholecystitis are due to infection with the colon bacillus and are the result of an ascending infection to the gallbladder from the duodenum.

Metabolic disturbances may affect the excretion of either bile pigment or cholesterol. Small irregular, dark brown or almost black stones composed of pigment and calcium with only slight, if any, degree of accompanying cholecystitis are frequently found in patients with congenital hemolytic jaundice. According to Giffin³⁵ they occur in 58 per cent of such cases. In this condition it is recognized that there is a marked pleochromism of the bile as a result of the excessive excretion of bile pigment. Greene and Snell³⁶ found in dogs that the intravenous injection of bilirubin or of hemoglobin increased the excretion of pigment in the bile but that significantly this augmented rate of excretion was brought about primarily by an increase in concentration. They report two experiments in which the concentration of bilirubin in the hepatic bile rose to 1,000 mg per hundred cubic centimeters or from six to twenty times the usual normal values.

Similarly concentrated bile has been observed in dogs following the experimental production of anemia by the administration of phenylhydrazine. If such concentrated bile remains in the gallbladder long enough to undergo much further inspissation, it would not be surprising if deposition of the excess pigment and calculus formation should occur.

Disturbances in cholesterol metabolism frequently result in the formation of gallstones. The waxy, glistening gallstone composed of a radiating mass of cholesterol crystals is most characteristic, but, according to McNee,³⁷ only some 6 per cent of gallstones are of this type. Twenty per cent are combination stones in which a cholesterol stone serves as a nucleus for the subsequent deposition of pigment and calcium, 64 per cent are mixed stones built up of concentric layers of cholesterol, pigment and lime salts. It is frequently assumed that the pure cholesterol stone is deposited as the result of a primary metabolic disturbance which may be independent of any element of cholecystitis. The effect of infection in causing the deposition of pigment and calcium is evidenced in the mixed types of stones. Pickens, Spanner and Bauman³⁸ have recently pointed out that gallstones, on the average, consist of 94 per cent of cholesterol with only some 3 per cent of pigment and 1 per cent of calcium present. Under these conditions the importance of cholesterol and of disturbances of cholesterol metabolism in the formation of calculi is obvious.

A tremendous amount of work has been done on different phases of cholesterol metabolism, but here also there is no final agreement as to the origin, function or fate of this material. According to the recent review of Muller³⁹ it is probable that the cholesterol in the body is both endogenous and exogenous in origin. The relative importance of these two sources has not been finally determined, though most observers consider that the greater proportion of the cholesterol is absorbed from the food and is excreted in the bile. A smaller amount is excreted in the bowel. The presence of bile in the intestine favors the absorption of cholesterol but is not essential thereto.

According to this view the liver has a regulating function and is active in maintaining the cholesterol content of the blood at a fairly constant level. In some types of hepatic disease, especially when biliary obstruction is present the cholesterol content of the blood is increased, while that in the bile is reduced. Normally, apart from the diurnal variations pointed out by Bruger and Somach,⁴⁰ it is difficult to affect the cholesterol level of the blood though slight and transient increases may be produced by a meal rich in cholesterol, particularly if fats are fed in addition. There is considerable evidence that, with the prolonged use of foods rich in cholesterol, hypercholesteremia develops and is accompanied by an increased excretion of cholesterol in the bile. Independently of the cholesterol intake diets rich in fats or any other measure that produces an increase in the fat content of the blood also produce hypercholesteremia. Diets low in cholesterol especially if they are low in fat as well, lead to a reduction in the cholesterol content of the

blood. If hypercholesteremia is present such diets frequently produce a return to normal but do not reduce the cholesterol content of the blood below normal. We have found hypercholesteremia in a large proportion of patients with chronic cholecystitis or cholelithiasis without biliary obstruction. The bile cholesterol is increased in some but not all cases. In these cases a diet low in cholesterol and at times the use of repeated duodenal drainages frequently results in a return toward normal of the blood cholesterol associated with an improvement in the clinical condition of the patient.

There is a definite sex difference in the incidence of cholecystitis and cholelithiasis, and various factors have been proposed to explain the greater frequency in females. Two of the most important of these are obesity and pregnancy.

In obesity there seems to be a disturbance in cholesterol metabolism, but a definite relation between the cholesterol content of the blood and the degree of obesity has not been established. Rapid weight reduction or starvation with mobilization of fat apparently liberates considerable quantities of stored cholesterol and produces a resultant hypercholesteremia. Under these conditions it should be emphasized that while weight reduction is important in the obese patient it should be gradual, and care should be taken to avoid stasis during the period of reduction.

Hypercholesteremia also occurs in pregnancy, apparently this is due in part to retention for, according to Pirbram⁴¹ and to Bacmeister,⁴² the bile cholesterol is at first reduced. In the later months of pregnancy and post partum the retained cholesterol was found by McNee⁴³ and Bacmeister to be eliminated in part in the bile. Bodily activity is apt to be reduced during pregnancy and constipation is usual. In addition Mann and Higgins⁴⁴ have recently shown that the muscular activity of the gallbladder is diminished in pregnant animals. All these factors promote biliary stasis and so favor the formation of calculi and the development of biliary infection during pregnancy.

The fundamental requirement for satisfactory results in the treatment of gallbladder disease is a correct initial diagnosis. A careful and complete diagnostic work-up is essential, for there is no one method of diagnosis that is infallible. In the majority of patients, symptoms are usually indefinite. Typical colic is by no means always associated with stones. Physical examination is frequently of little assistance except in acute conditions or in cases of jaundice. The limitations of cholecystographic study must be recognized, for a diseased gallbladder may visualize and empty normally even though stones are present. Conversely, there may be no visualization on repeated cholecystographic examination and still laparotomy may reveal an apparently normal gallbladder. We have found nonsurgical biliary tract drainage a valuable supplementary method of diagnosis, provided the drainage is properly performed and the results are correctly interpreted, particularly in regard to the absence of concentrated bile or the presence of pathologic elements in the biliary sediment.

The selection of a group of 500 patients as having gallbladder disease has been made in the clinic for diseases of the biliary tract at the New York Post-Graduate Hospital, in accordance with the complete diagnostic routine described elsewhere.¹⁰ In addition to the examination of the biliary tract, other tests such as urinalyses and blood counts have been done as a routine. When indicated, roentgenologic studies of the gastro-intestinal or urinary tracts have been made. The patients who gave evidence of biliary tract disease only have been studied over a period of three years the initial diagnostic study being repeated periodically to determine the effects of treatment and to correlate these observations with the clinical course of the disease. Details as to the results of the treatment will be published in a subsequent paper.

The general plan of medical treatment followed in these patients has been based on consideration of the foregoing principles and may be considered under the heading of (1) prevention of biliary stasis, (2) prevention or treatment of inflammation of the gallbladder or bile ducts, (3) diet and (4) removal of calculi when once formed. So far, progress other than surgical in this last type of therapy has been nil and need not be considered further.

The value of attention to the general hygiene of the patient, of regular habits, moderate exercise, deep breathing, avoidance of constipation, freedom from mental strain and worry and the like has been amply demonstrated by experience. In the past this improvement has been ascribed largely to the relief of biliary stasis. Horseback riding has long been favored to stir up a sluggish liver and cause emptying of the gallbladder. In the light of present knowledge of the physiology of the biliary tract, it would seem now that the value of such measures is to be ascribed as much to the improvement in muscular tone and the state of the general health of the patient as to any specific action on the gallbladder. This remark however is not to be interpreted as in any way minimizing the importance of such general measures.

Removal of foci of infection, particularly as regards the teeth and tonsils, is important as a means of preventing or treating infection in the biliary tract. Hurst,⁴⁵ among others, has emphasized the importance of attacks of indigestion or acute gastritis in permitting ascending infection of the biliary tract, particularly with colon bacilli. He also stresses the value of methenamine as a biliary antiseptic in such cases.

Various spas have long been favored for the treatment of diseases of the liver and biliary tract. Apart from regulation of the hygiene of the patient and the use of diets, this type of therapy depends on the use of mineral waters. These contain saline cathartics in varying amounts the active agent usually being magnesium sulphate, sodium sulphate, sodium phosphate or a mixture of these salts. It is now accepted that saline cathartics as well as the ever popular calomel have little action in stimulating the secretion of bile, but they prevent constipation ensure regular action of the bowels, and favor emptying of the gallbladder. The use of duodenal drainage also facilitates the latter. This is a valuable diagnostic procedure, but questions of time and expense lessen its value as a routine therapeutic measure.

Alkaline powders when given before meals frequently relieve reflex gastric symptoms. Sedatives such as phenobarbital or bromides give excellent results, espe-

cially in nervous or neurotic patients. The use of these drugs with antispasmodics or alkalis at times is especially effective. We have used cholagogues with symptomatic relief in some cases, sodium dehydrocholate being the preparation usually given.

While the occurrence of a typical biliary colic followed by jaundice is diagnostic, it usually indicates the presence of gallstones and the need for surgical rather than medical management of the patient. The early symptoms of cholecystitis, the "inaugural symptoms of cholelithiasis" of Moynihan,³⁶ are not localized to the biliary tract. Much of the epigastric fullness and distress, the flatulence and nausea of which these patients complain is due to disturbances in the activity of the stomach, duodenum and bowels, produced partly as a result of secondary reflex disturbances and partly as a result of interference with normal digestion. This relationship has been pointed out by von Noorden and Salomon,⁴² Chester Jones,⁴⁰ and recently discussed in detail by Alvarez.¹

Von Noorden⁴⁷ has called attention to the secretory disturbances of the stomach and intestinal tract which he attributes to catarrhal conditions. He states that gastric hypo-acidity may not produce any symptoms but nevertheless has an effect on the biliary tract, particularly in regard to the loss of protective action against external bacterial invasion. Hyperacidity, he feels, is more frequently associated with pain and furthermore produces excessive stimulation of the bile flow. This can be prevented by regulation of the acidity. Von Noorden⁴⁷ also calls attention to the frequent association of the "lazy colon" with gallbladder disease. The importance of the spastic sigmoid is emphasized particularly, for it sometimes causes colic which may be mistaken for biliary colic.

The value of frequent small meals and of a bland nonirritating diet that is free from coarse fiber and leaves only a small residue is generally accepted as basic in the treatment of chronic cholecystitis and the associated gastro-intestinal disturbances. The various topics previously discussed in this paper, however, show that no single diet is applicable to the management of all patients.

When the patient is obese, reduction in weight is imperative. In this case fats should be eliminated from the diet and the intake of cereals and starches reduced to keep the total intake of food below the caloric requirements.

A certain proportion of patients with disease of the biliary tract complain of intolerance to food. Some have been literally afraid to eat and are semistarved and underweight in consequence. In such cases the bland diet is important. In addition, when the patient is underweight every effort should be made to increase the caloric intake. Frequent feedings either four or five small meals daily or the use of intermediate nourishment between the usual three meals, a liberal intake of starches and cereals and, if possible, the addition of cream, butter or olive oil to the diet is desirable to facilitate gain in weight.

In some instances the intolerance to food is due to reflex gastric disturbances with the development of the syndrome of hyperacidity which is usually considered

characteristic of peptic ulcer. In such cases a modified ulcer type of management with or without the use of alkalis is indicated.

Many patients show a definite intolerance to fats. The importance of bile in the absorption of fats has long been known. This is partly due to its action in activating the pancreatic lipase, partly to the action of the bile salts in favoring emulsification and solution of the fats and partly, as more recently emphasized by Wieland and Sorge⁴⁸ and by Verzar and Kuthy,⁴⁹ to the formation of addition compounds between the bile salts and the fatty acids, which are thereby absorbed directly into the portal blood stream.

Friedrich von Muller⁵⁰ long ago showed the great diminution in the absorption of fat that occurs in the presence of complete biliary obstruction. Many patients with cholecystitis complain of discomfort following a fat meal, which is probably best explained by the effect of fats in stimulating the formation of cholecystokinin. This stimulates the gallbladder to contract and, in the presence of active inflammation or of any disharmony in the reciprocal action of the gallbladder and the sphincter of Oddi, may well cause pain. On the other hand, if there is no intolerance, cream, egg yolk, olive oil or oleic acid are valuable additions to the diet, for

TABLE 1—Cholesterol Content of Various Foodstuffs

Food	Per Cent	Food	Per Cent
Brain cattle	37.27	Rabbit whole	0.117
Liver	34.03	Bacon fat	0.108
Kidney mutton	34.03	Corn sweet	0.100

in the presence of a functionally competent gallbladder they stimulate the formation of cholecystokinin and aid biliary drainage.

The significance of hypercholesteremia in relation to the possible formation of gallstones has already been discussed. The routine determination of the cholesterol content of the blood is a valuable procedure in these patients. When this value is increased, foods rich in cholesterol, such as brain, eggs, butter, goose, duck, liver, sweetbreads or cream, should be excluded from the diet.

The cholesterol content of various foodstuffs is given in table 1. This represents a compilation of the majority of values given in the literature⁵¹ for the cholesterol content of food. Many of the analyses are old. There is no distinction between cholesterol and other sterols. The need for a more accurate and comprehensive series of analyses is obvious. In the past, beans and peas have been proscribed, but Schoenheimer⁵²

has recently pointed out that while they contain considerable amounts of sterol the latter is not cholesterol but phytosterol which is not absorbed by the mammalian intestine. These vegetables may therefore be included in the diet. In addition, the fat content of the commoner foods is given in table 2.

These tables have been used in the selection of a series of diet lists embodying the principles here discussed. Their usefulness has been amply demonstrated in practice, as they have been in use for over three years.

The general principle of a bland diet is followed in each of the five diets. The first three diets are limited in cholesterol and fat intake and are indicated for those patients having an intolerance to fats, active inflammation of the gallbladder, a nonfunctioning gallbladder (as shown by biliary tract drainage and lack of visualization on cholecystographic study), a hypercholesteremia or cholelithiasis. Diet 1 has a low caloric value for use in obese patients. Diet 2 differs from diet 1 in that it has an increased carbohydrate and caloric value and is therefore useful in underweight patients as well as in cases of cirrhosis of the liver or jaundice. Diet 3 differs in the more strict avoidance of all stimulating and irritating foods and is used for patients having excessive gastric hyperacidity. Diets 4 and 5 are relatively high in cholesterol and moderately high in fat content; these diets are used to stimulate the evacuation of the gallbladder in patients having an atonic or poorly functioning gallbladder (with patent cystic duct) without fat intolerance, hypercholesteremia or cholelithiasis. Diet 4 is low in caloric value (for obese patients). Diet 5 is high in carbohydrate and caloric value.

These diet lists are not to be considered all inclusive. The importance of individualization in the management of each patient is to be stressed.

General Directions for Use With the Gallbladder Diets

Meals	Meals should be small in amount and taken at the same time each day. Large meals and overeating are detrimental. Chew all food carefully; the teeth must be in good condition.
Rest	A rest of a half hour lying down should be taken after the noon and evening meals. This allows the food to digest which is impossible with mental or physical work immediately following meals.
Bowel Movements	An effort should be made to move the bowels every day after breakfast regardless of inclination. If the bowels do not move every day this should be reported to the physician so that medication may be prescribed.
Exercise	A proper amount of outdoor exercise is essential for the proper functioning of the gallbladder and all other organs. A walk of at least forty blocks should be taken every morning, deep breathing being taken at this time to stimulate the action of the gallbladder.
Water	At least eight glasses of water are to be taken daily. A glass of water preferably hot should be taken on arising in the morning. The other water should be taken between meals rather than with meals.
Medication	As directed by the physician.

DIET 1—Low Cholesterol, Low Fat, Low Caloric

Breakfast

Fruit	Orange juice, baked apple, apple sauce or stewed prunes with a little sugar and milk, no cream.
Eggs	One egg may be taken three times weekly, soft boiled or poached with a thin slice of lean crisp bacon.
Bread	A half slice of toasted white bread with a little marmalade, jelly or jam.
Beverages	A small cup of coffee, Sanka coffee, Postum or tea with 1 teaspoonful of cream, 1 lump of sugar.

Lunch and Dinner

Soups	A small portion of consommé, chicken, tomato or clear vegetable soup may be taken once daily. No creamed soups or fats.
-------	---

Meats	A small portion of lean meat or fish twice daily. Meats: Roast beef, lamb (leg), chicken, ham. Fish: Cod, trout, halibut, weakfish, bluefish, blackfish, flounder, striped bass, red snapper.
Vegetables	Two green vegetables daily, as spinach, peas, beans, beet tops, asparagus, string beans or beets, carrots, squash, boiled mushrooms, stewed tomatoes, stewed celery, boiled okra. Not prepared or eaten with butter or cream.
Salads	Lettuce with stewed fruits or with cooked vegetables. Liquid petrolatum or lemon dressing.
Bread	As above.
Beverages	As above or a small glass of buttermilk.
Desserts	Stewed fruits, as peaches, pears, plums, cherries, grapes, prunes, pineapple or apple sauce. Gelatin, fruit ice, prune soufflé.
Avoid	Butter, cream, meat fats, grease, gravies. All foods fried, hashed or warmed over. Inner organs, as brain, liver, kidneys, sweetbread. All rich and highly seasoned foods, creamed food, and foods prepared with cream, butter or eggs. Oils, as olive oil, cod liver oil, salad dressings. Heavy cheeses, nuts, olives, spiced foods. Candies, cakes, pies, pastries, chocolate, cocoa. Cold food, condiments, alcohol, smoking. Rough foods, as cabbage, cucumbers, pickles, bran and whole wheat products. With digestive disturbances, salads, raw fruit and raw vegetables should be omitted; all vegetables should be pureed.

DIET 2—Low Cholesterol, Low Fat, High Caloric

Breakfast

Fruits	Orange juice, baked apple, apple sauce or stewed fruit, as prunes, pear, peaches with milk and sugar.
Cereals	Cooked as farina, cream of wheat, wheatena, oatmeal, rolled oats with milk and sugar.
Eggs	One egg may be taken three times weekly, soft boiled or poached on toast with 2 slices of lean crisp bacon.
Bread	Two slices, toasted white bread, rolls or corn bread with jam, marmalade or jelly.
Beverages	Milk, half milk and coffee, Sanka coffee, Postum or weak tea with 1 teaspoonful of cream and 1 lump of sugar.

Lunch and Dinner

Soups	Small portions of tomato, chicken, plain vegetable, gumbo or oxtail.
Meats	Lean meat or fish at least once daily. Meats: Roast beef, chicken, lamb or mutton. Fish: Cod, trout, weakfish, whitefish, bluefish, flounder, striped bass, blackfish, red snapper.
Vegetables	Potatoes, baked, mashed or boiled, or sweet potato, macaroni or spaghetti, spinach, peas, beans, beet greens, beets, carrots, squash, asparagus, boiled mushrooms, string beans, stewed tomatoes or celery. Not to be eaten or prepared with butter or cream.
Salads	Lettuce with stewed fruits, canned fruits or cooked vegetables with liquid petrolatum or lemon dressing.
Bread	As above.
Beverages	As above or malted milk.
Desserts	Puddings, as bread, tapioca, cornstarch or sago. Stewed fruits, as peaches, pears, plums, prunes, berries, apple sauce, baked apple with milk and sugar. Gelatin, junket, baked banana, plain cake.
Intermediated foods	A glass of milk, malted milk or Ovaltine to be taken at 10 a. m., 4 p. m. and at bedtime. With zwieback, plain or arrowroot crackers, breadsticks or toast, jelly or marmalade may be added if desired.
Avoid	Foods listed to be avoided in diet 1.

DIET 3—Bland, Low Cholesterol for Gastric Hyperacidity

Breakfast

Fruits	Stewed or canned, as peaches, pear, apricots, prunes. Baked apple, apple sauce, no sugar added.
Cereals	Cooked as farina, cream of wheat, wheatena, strained oat meal with milk and little sugar.
Eggs	One egg, soft boiled or poached on toast with a slice of lean crisp bacon if desired.
Bread	One slice of toasted white bread with marmalade or jelly.
Beverages	Milk, Postum, weak tea with milk and sugar.

Lunch and Dinner

Meats	Lean meat or fish twice daily, not fried. Meats: Roast beef, chicken, lamb, ham, chopped meat. Fish: Cod, trout, weakfish, whitefish, blackfish, flounder, striped bass, haddock, plaice.
Vegetables	Potatoes, baked, boiled or mashed. Macaroni or spaghetti, no sauce. Vegetables, pureed only, as carrots, beet, spinach, peas, beans, asparagus, tips, squash.
Salads	Lettuce with stewed fruits or cooked vegetables. Liquid petrolatum dressing.
Bread	As above.

Beverages	Milk or malted milk
Desserts	Puddings as cornstarch bread tapioca fruits as pear= peaches= prunes= cherries banana
	Sago Stewed Gelatin Baked
Avoid	Foods listed to be avoided in diet 1

DIET 4—*High Cholesterol, Low Caloric*

Breakfast

Fruits	Orange juice or stewed fruits as peaches pears prunes Baked apple apple sauce with cream and sugar
Eggs	One egg (oft boiled or poached) may be taken daily with a slice of lean crisp bacon
Bread	A half slice of toasted white bread with butter
Beverages	Milk tea coffee or Postum with cream and sugar

Lunch and Dinner

Soups	A small portion of consommé vegetable oxtail pea or tomato soup may be taken once daily
Meats	A small portion of lean meat or fish twice daily Meats Chicken roast beef, lamb chop leg of lamb mut- ton or veal Fish Cod trout halibut weakfish whitefish flounder Brains liver kidneys or sweetbreads three times weekly
Vegetables	Two at each meal (preferably green) as spinach asparagus string beans beet green carrots squash stewed tomatoes celery or okra
Salads	Lettuce with canned or stewed fruits Liquid petrolatum
Bread	As above
Beverages	As above
Desserts	Stewed fruits as peaches pears pineapple cherries Gelatin stewed fruits apple sauce prune soufflé
Avoid	All foods fried hashed or warmed over Rich and highly season foods spices condiments Heavy cheeses nuts olives pickles Candies cakes pies pastries chocolate cocoa Rough foods as cabbage cucumbers, bran and whole wheat products With digestive symptoms salads raw fruits and raw veg- tables should be omitted all vegetables should be pureed

DIET 5—*High Cholesterol High Caloric*

Breakfast

Fruits	Orange juice stewed or canned fruits or prunes Baked apple apple sauce with cream and sugar
Cereals	Cooked as wheatena cream of wheat farina oatmeal with cream and sugar
Eggs	Two soft boiled or poached eggs daily with two slices of lean, crisp bacon
Bread	Two slices of toasted white bread with butter
Beverages	Tea (weak) milk Postum with cream and sugar

Lunch and Dinner

Soups	Consommé creamed tomato vegetable oxtail
Meats	A small portion of lean meat or fish Meats Lamb chops roast lamb leg of lamb chicken or other fowl roast beef steak Fish Shad trout halibut weakfish whitefish pike flounder bass blackfish Brains liver kidneys or sweetbreads three times weekly
Vegetables	Baked boiled or mashed potato with cream or butter or macaroni or spaghetti Spinach asparagus carrot beet beet greens squash boiled mushrooms stewed tomatoes
Salad	Lettuce with stewed fruits or cooked vegetable Mayon- naise liquid petrolatum or kumondrelax
Bread	Two slices toasted white bread with butter
Beverage	As above
Desserts	Custard pudding as rice tapioca bread Stewed fruits or canned fruits with crackers Baked apple apple sauce with cream and sugar Plain cake ice cream junket gelatin
Olive oil	A teaspoonful of olive oil to be taken a half hour before each meal this amount is to be increased a teaspoonful each week until a tablespoonful is taken before each meal
Intermittent doses of oil	A glass of milk melted milk asq. nor or castor oil to be taken at 10 a m 4 p m and at bedtime with zaklax cacker 10a 1 or breadstick Butter or jam if desired
Avoid	Foods listed to be avoided in diet 4

CONCLUSION

If due attention is given to the physiologic disturbances responsible for the symptoms of which the patient complains and if physiologic principles are kept in mind during the treatment improvement is possible in the present medical management of diseases of the gallbladder and biliary tract

65 La Fite Fifth Street—889 Lexington Avenue.

ABSTRACT OF DISCUSSION

DR SIDNEY A. PORTIS, Chicago It is important to devise some medical measures for handling these patients so that they get symptomatic relief. It is difficult to evaluate very early in the disease which gallbladders will respond to medical management and which may need surgical intervention. The test of time is probably the best method of evaluating which should be the course. Certain patients seem to respond better to very high carbohydrate and low fat diets, but in the undernourished a moderate amount of fat may be definitely indicated. I have found a large number of overweight obese patients, particularly women around 35 to 45, suffering from an associated hypothyroidism. Routine basal metabolic tests in these women have shown a rate of minus 15 20 25 or 30. The addition of small doses of thyroid extract to the medication seems to be particularly effective in raising the metabolism. It is well known that in hypothyroidism there is a sluggish movement of the gastro-intestinal tract. There is a group of patients who have a sensation of nausea, vertigo, fullness and distention, which seem to be related to the movements more of the first and second portion of the duodenum. I have found that hydrochloric acid may be particularly effective in promoting the movements of the upper intestinal tract in these patients in spite of the fact that they have normal, sometimes slightly increased and sometimes slightly decreased acidity in the stomach. Many of these patients have become comfortable under this management. The important cardinal feature to remember in gallbladder disease is that one must protect the liver function. I know of no better method of protecting liver function than by the use of carbohydrates. I could find no appreciable elevation of blood cholesterol after feeding patients 3 Gm of cholesterol and concluded that the reason for this presumed hypocholesteremia was the inability of the liver to form the cholesterol ester fraction from the cholesterol. This was first brought out by Epstein, working at the Mount Sinai Hospital.

DR C. B. WRIGHT, Minneapolis I should like to ask whether there was any definite evidence that attacks of cholecystitis were prevented by this method of treatment.

DR W. D. MAYR, Detroit I should like to ask whether the authors use nonsurgical drainage of the gallbladder at all in their treatment.

DR F. W. MULLSOW, Cedar Rapids, Iowa What evidence do the authors have that bile salts stimulate the liver? The reason I ask is that I am circularized by drug houses to buy bile salts for all kinds of gastro-intestinal disturbances and especially in gallbladder disease. I can't find much evidence of bile salts helping in constipation. I don't know that it stimulates the liver.

DR CARL H. GREENE, New York It is our impression that in many cases duodenal drainage, perhaps by relieving biliary stasis, is of therapeutic value. Dr Wright's question as to the number of attacks of cholecystitis that have been prevented is difficult to answer because of the silent gallstone. I don't think that anybody can explain all the factors that determine why the gallstone is silent or why it causes symptoms. One can show experimentally by giving bile salts intravenously in an animal with a bile fistula or giving bile salts orally to animals with a bile fistula that it results in an increase of flow of bile with secretion of the given bile salts after four to six hours. On the other hand from the clinical standpoint the relation of the flow of bile to such factors as constipation is difficult to answer. Most of the pharmaceutical houses recommend tablets that are essentially homeopathic so far as the dose is concerned. The matter of the clinical use is by no means settled and requires further work for its elucidation. The point that Dr Thiss and I want to emphasize is that by taking advantage of the known physiologic facts and by the individualization of the patient from the standpoint of idiosyncrasy and interpretation of the clinical syndrome the methods of medical management can be improved. It is to be hoped that it will be possible to improve methods still further because it is only by early diagnosis and treatment that I see any prospects of the prevention of gallstones. Until that question is solved the medical treatment of biliary tract disease cannot hope to supplant the surgical treatment.

THE PRACTICAL APPLICATION OF EXCRETORY (INTRAVENOUS) UROGRAPHY

WILLIAM F. BRAASCH, M.D.
ROCHESTER, MINN.

The name of this new method of urographic visualization, which has become one of the most valuable aids in clinical diagnosis, deserves consideration. Since its inception it has been most often referred to by the term "intravenous urography," which was adopted to distinguish it from "cystoscopic" or "retrograde urography." It has also been referred to as "descending" or "excretion urography" by European observers. "Excretory urography" would seem the logical term since it is physiologically descriptive and in view of recent and portending advances in oral administration, would be quite acceptable.

The members of the medical profession have been inexcusably slow in availing themselves of the opportunities offered by excretory urography in the diagnosis of abdominal lesions. Judging from the frequent requests made by patients for excretory urography rather than cystoscopy, it might be inferred that laymen are more familiar with the method than some physicians. It should and probably will be employed in the near future as a routine method in the diagnosis of abdominal conditions. Probably the greatest obstacle to its general employment has been the problem of urographic interpretation. This will, no doubt, always limit its general use largely to fields in which changes in the outline of the renal pelvis will be so extensive that the lesion is easily recognized. Nevertheless, many of the deformities of the renal pelvis will soon be roentgenologically standardized in a manner similar to lesions of the alimentary tract, so that any one with roentgenographic experience should be able to interpret most urograms with a fair degree of accuracy. Errors in interpretation undoubtedly will arise, and the necessity for correlation with cystoscopic and other data will often be present. However, excretory urography will no doubt make it possible for the general clinician to recognize many lesions that would otherwise be overlooked or that were formerly discovered only with the aid of complicated urologic apparatus. The excretory urogram will be of greatest practical value to clinical diagnosis in (1) determining the presence of stasis in the renal pelvis or ureter, (2) aiding in interpretation of shadows in the upper part of the urinary tract, and (3) giving a fairly accurate estimate of renal function.

The change in attitude among urologists toward excretory urography is of considerable interest. Following the pioneer work of Rowntree and his associates, the practical application by Roseno¹ and by Swick,² and the clinical contributions by von Lichtenberg and Swick,³ the method at first was received with skepticism and apprehension. However, as its clinical value was demonstrated their attitude changed completely, and now there are a few urologists who go so far as to

claim that the cystoscope is no longer necessary in the diagnosis of renal lesions. It is true that excretory urography has replaced the former methods of urologic investigation to some extent. It should be stated, however, that retrograde urography is still of great value particularly in the recognition of minor deformity, and has supplied data that could be acquired in no other way. The data obtained from the combined use of excretory and retrograde urography will often give more complete information than when either method is used alone. On the other hand, it must not be inferred that visualization of the renal pelvis and ureter will give all the data that are necessary to complete clinical appraisal. Other than accurate urographic interpretation, often there are data of equal importance which only an experienced urologist can supply.

Excretory urography is frequently disappointing because of inadequate visualization of the pelvis and calices. Often in a case in which clear visualization is most needed the pelvic outline is so dim and uncertain as to render exact interpretation impossible. Failure of visualization may be due to a lesion in the kidney, rapidity of excretion and excessive peristalsis or a technical factor, and its cause may be difficult to determine. Complete failure of visualization on one side in repeated films must be interpreted as indicative of renal dysfunction. It is of importance to determine whether the dysfunction is secondary to some temporary lesion or irritant that can be corrected or whether the renal tissue is actually destroyed. With failure of visualization it is often advisable to corroborate evident dysfunction by means of cystoscopic inspection of the ureteral orifice and with the aid of dye tests. An approximate appraisal of the pelvic outline can be obtained often by piecing together the combined data obtained from several films taken at different intervals. One of the dangers of dim visualization, however, is that the interpreter is likely to take too much for granted and assume a condition to be normal or abnormal from insufficient data. The mere fact that pelvis are visualized, even though incompletely, will often be sufficient to demonstrate that function remains to the kidney. When advanced disease of the kidney has been surmised from the preliminary clinical or cystoscopic data the value of visualizing a comparatively normal pelvic outline, even though incompletely, is self evident.

Fairly clear visualization on one side and poor visualization on the other, does not necessarily indicate a lesion in the latter side. In fact, a pelvis that is incompletely visualized may easily be confused with deformity, and in the hands of an inexperienced observer more harm than good may be done.

A difference in the degree of visualization of the two kidneys is often observed when no other evidence of change is apparent. There may be also a difference in the time of visualization, one pelvis being much better visualized in the first film and the other in a later film. There also is variation in the time of emptying. When the latter is very much retarded it usually indicates stasis resulting from actual obstruction, or from atonic changes caused by an active lesion or one previously present but now healed. Exact interpretation of moderate delay in visualization may be difficult.

HYDRONEPHROSIS

Excretory urography permits clinical recognition of hydronephrosis by means of a comparatively simple method and as a result many cases of hydronephrosis

From the Section on Urology, the Mayo Clinic.
Read before the Section on Urology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.

are being diagnosed by the general practitioner which otherwise would be overlooked. Recognition of the deformity in the outline of the renal pelvis caused by well defined hydronephrosis should not be difficult, even to a physician who has had limited experience in roentgenographic interpretation. Although it is true that there may be some difficulty in the interpretation of slight pyelectasis (fig 1) and in complicating deformities, there are few obstacles to general interpretation in most cases in this field.

One of the advantages of the excretory urogram is the ability it gives to compare the outline, time of appearance and disappearance, and degree of visualization of the two renal pelvises, these data are of considerable importance in determining whether minor degrees of stasis are present. In a large number of cases, pyelectasis is bilateral. Although it is usually much greater on one side, there will often be evidence of a variable degree of pyelectasis or other deformity on the other side. It occasionally happens that, although the symptoms will be referred to one kidney, the degree of pyelectasis in the other side may be of equal or greater extent. Visualization of the dilated pelvis may be retarded and dim in the early films and completely visualized only in later films. With extensive hydronephrosis, visualization of the pelvis is often retarded and may be inadequate even in the late films. At times, only a few dilated calices are outlined, and in some cases no evidence of the injected dye is visible until one or two hours after injection. With rapid excretion of the dye and unobstructed drainage while the urogram is being made, the complete extent of the hydronephrosis may not be visualized, and in such cases the pyelectasis may be more completely visualized by the retrograde method. In all doubtful cases it is advisable to visualize the pelvis by both retrograde and excretory urograms. In the course of routine urography, minor degrees of pyelectasis are often observed which have caused no symptoms and apparently are of no clinical significance.

Excretory urography gives the surgeon an excellent opportunity to follow the results of operation on the hydronephrotic pelvis. The changes in the pelvic outline visualized subsequent to plastic operation are often of considerable interest and give a valuable indication of the results.

RENAL PTOSIS

Although the presence of renal ptosis usually can be determined in the course of abdominal palpation, the comparative degree of ptosis and of the excursion of both kidneys in varying positions can be determined more accurately in the excretory urogram. In the course of abdominal examination, evidence of ptosis of only one kidney often is found whereas in the excretory urogram ptosis of equal degree is often found on both sides. Renal ptosis usually can be determined without the aid of urography, but not the indications for operation. It is now generally recognized that unless there is definite evidence of renal stasis nephropexy is usually not indicated. Excretory urography offers an ideal method for determining minor degrees of stasis. Comparative delay in time and degree of visualization or in emptying on the side involved may be of considerable diagnostic importance. Should these data be found on the side opposite to the localization of pain as occasionally happens, the situation may be confusing. It may be surmised that if excretory urography is employed in all cases of renal ptosis in which

surgery is contemplated, in order to determine the comparative degree of ptosis and the presence of stasis, only few operations for nephropexy will be performed.

RENAL LITHIASIS

Excretory urography is probably more often of value to the general practitioner and surgeon in the diagnosis and study of lithiasis than in any other field. The excretory urogram permits identification of shadows seen in the renal area in the flat film. It also establishes their intrarenal situation and allows visualization of coincident complications and of the relative functional capacity of either kidney. In fact, all the data necessary for operation are evident without cystoscopic examination in the majority of cases of renal lithiasis, and with these data the surgeon can proceed with assurance. However, many cases of renal stone remain in which the cystoscope will be of value. When there is a history of or evidence of gross hematuria or pyuria,

Fig 1.—Excretory urogram showing bilateral pyelectasis more marked on left side.

cystoscopy usually will be advisable in order to determine the source. If there is a shadow suggestive of unilateral renal calculus visible in the flat film and there is evidence of pyuria or hematuria, it does not necessarily follow that the latter has its origin in the kidney containing the stone. Not only will the other kidney have to be excluded from consideration, by cystoscopy, but the lower part of the urinary tract as well. Some difficulty may arise in interpreting the nature of the original shadow when the excretory urogram gives no evidence of pyelectasis or stasis. This may occur if stones are of large size and of long standing. If the shadow is small it may be in line with the pelvis but may not be visible within the pelvic shadow. In such cases it is well to repeat the films at different angles and with a lateral exposure. In some cases, cystoscopy may be of value. As a rule however difference in the degree of visualization of the two pelvises with evidence of renal stasis in the affected kidney, difference in time of appearance and disappearance of visualization, and pyelectasis or ureterectasis on the affected side will give

the necessary diagnostic data. It is surprising, in the course of routine excretory urography in cases of lithiasis, how often some evidence of disease is found in the other kidney. Minor degrees of pyelectasis or ureterectasis frequently are visualized as a result either of a previously existing stone or of infection.

Fig. 2—Excretory urogram showing deformity accompanying polycystic kidney.

ABDOMINAL TUMOR

Among the problems in diagnosis most commonly observed in general practice is the identification of a tumor palpated in the upper lateral part of the abdomen. In the absence of other diagnostic data it may be impossible to identify the tumor by the methods usually employed in physical diagnosis. The excretory urogram often will give sufficient data either to identify it as renal or to exclude the possibility of its being renal. Visualization of filling defects in the pelvic outline, or of elongation and deformity of involved calices or failure of visualization on the side of the abdominal tumor is usually sufficient to justify the inference that the tumor is intrarenal. On the other hand a normal pelvic outline usually will exclude the possibility of the tumor being renal. It should be emphasized, however, that, if the details of the calices are not clearly visualized, exact interpretation is impossible and cystoscopic data, together with a retrograde urogram, are necessary. Error in the diagnosis of renal tumor is easily made by trying to interpret an excretory urogram in which the details of the calices are inadequately visualized. In cases of doubt, a retrograde urogram should always be made.

Excretory urography, when feasible, is distinctly preferable to retrograde urography in the diagnosis of polycystic kidney (fig. 2), because it obviates the danger of infection secondary to ureteral catheterization or retrograde urography. Although deformity suggestive of polycystic kidney is often clearly visualized in the excretory urogram, in many cases the visualization is inadequate for interpretation, either because of abnormal excretion or because of subnormal renal

function. It has been my experience that, when the concentration of urea is more than 50 or 60 mg. in each 100 cc. of blood, visualization is unsatisfactory.

RENAL TUBERCULOSIS

The question often arises, How far can physicians rely on the evidence given by excretory urography in the diagnosis and localization of renal tuberculosis? As a rule, renal tuberculosis will cause some degree of deformity in the excretory urogram. Although the abnormality may not be typical of renal tuberculosis, nevertheless, with the aid of other evidence such as the presence of acid-fast bacilli in the catheterized urine, a diagnosis frequently can be established. When any of the following signs are observed in the excretory urogram, namely, absence of or marked delay in visualization (fig. 3), irregular pyelectasis or ureterectasis, failure of visualization of one or more calices, with irregularity of the pelves, or definite necrosis on one side and a normal pelvis and ureter on the other, the diagnosis of renal tuberculosis often can be inferred. Often, subsequently, a retrograde urogram will give visualization of doubtful deformity much more clearly or will disclose deformity otherwise not seen. The question may be raised whether the particulars derived from an excretory urogram alone would be sufficient to warrant removal of the kidney involved without cystoscopic data. It should be stated that normal visualization on one or both sides would not exclude renal tuberculosis. On several occasions I have been able to find bacilli of tuberculosis and a few pus cells in the catheterized specimen of urine from a kidney which,

Fig. 3—Excretory urogram showing right renal tuberculosis. There is a difference in renal visualization; there is a filling defect in the upper calices of the right renal pelvis.

from excretory urographic evidence, would be inferred to be normal. Although it is usually advisable to corroborate the urographic evidence of a normal kidney on the opposite side by means of ureteral catheterization, nevertheless if for any reason cystoscopy would be difficult or impossible, a physician could, with a relative degree of assurance, advise removal of the kidney involved.

The possibility of error in inferring from an excretory urogram that a kidney is normal is illustrated by a case in which the patient presented himself because of indefinite backache, with no symptoms suggestive of disease of the urinary tract. A few pus cells were found in the urine and, when the sediment was stained,

Fig 4—Excretory urogram showing complete duplication of left renal pelvis, with pyelectasis in both pelvises, more marked in the lower

acid-fast bacilli or other bacteria were not seen. The general examination, including roentgenograms of the urinary tract and tests of renal function, was negative. An excretory urogram gave an average visualization of both pelvises, calices and ureters, which were interpreted as being normal. A diagnosis was made that the upper part of the urinary tract was normal. On subsequent examination a cystoscopic examination was made because of the persistence of a moderate amount of pus in the urine. In the catheterized specimen from the right kidney, a few pus cells were present and the stained sediment revealed a few acid-fast bacilli. It is evident, therefore, that the patient was suffering from tuberculosis of the right kidney, which would have escaped detection if excretory urography had been depended on for diagnosis.

MISCELLANEOUS

Among other conditions in which excretory urography is of diagnostic value should be mentioned the complications of pregnancy.⁴ Various observers have employed this method as a routine without apparent injury to the patient and have been able to find evidence of secondary lesions in the urinary tract in a surprisingly high percentage of cases. Excretory urography is often disappointing in the diagnosis of pyelonephritis since the deformity of the renal pelvis accompanying pyelonephritis may be so insignificant that it will not be adequately visualized. In many cases however as a result of atony or of secondary obstruction ureterectasis or pyelectasis will be visualized. Minor changes in the outline of the calices resulting from a previous infection now dormant are often observed in routine urography. With chronic unilateral pyelonephritis however the resulting deformity is often marked. It may be recognized by unilateral deformity such as incomplete visualization or ectatic deformity

of the pelvis with absence of one or more calices. With atrophic pyelonephritis the outline of the pelvis and calices is in keeping with the degree of renal atrophy, although minor pyelectasis may also be present. The existence of anomaly of the upper part of the urinary tract, such as renal fusion, duplication of the pelvis (fig 4) and ureter, renal dystopia, incomplete rotation and agenesis, will undoubtedly be discovered much more often than formerly. Since such anomaly is often complicated by some secondary lesion, the practical importance of preoperative visualization is self evident.⁵ Excretory urography should be employed as a routine in cases in which injury to the urinary tract is suspected. Although reflex inhibition of excretion following severe injury may interfere with interpretation, nevertheless the character and extent of rupture of the kidney may often be visible in the urogram. Rupture of the bladder may also be determined by the method better than in any other way and without the dangers of secondary infection.

RENAL LESIONS COMPLICATING VESICAL DISEASE

When lesions such as neoplasm, diverticulum, stone or prostatic abnormality involve the bladder, secondary complications often occur in the kidney and ureter and may be determined only by means of excretory urography. In fact, its employment as a routine is advisable in all surgical lesions involving the bladder and urethra, even though symptoms suggesting involvement of the upper part of the urinary tract may not be present. Unilateral absence or reduction of renal function, pyelectasis and ureterectasis are often found when

Fig 5—Excretory urograms showing stone in left ureter; there is evidence of pyelectasis and renal atrophy.

least suspected. Should a vesical neoplasm surround a ureteral orifice, it is of primary importance to determine, before operation, the condition of the ureter and kidney involved. When cystectomy and reimplantation of the ureter are contemplated the value of preliminary visualization of the ureter and renal pelvis is self evident.

EXCRETORY URETEROGRAM

Visualization of the ureter in the excretory urogram is often disappointing. Although the normal ureter usually is not visualized in its entirety, it occasionally will be outlined completely. As a rule visualization of the ureter is fragmentary, varying with the amount of iodized urine contained, and with systole and diastole. More commonly, the upper third of the ureter only is visualized although in subsequent films the other portions of the ureter particularly the lower third, can be seen. For this reason it is often necessary to assemble the data from several films in order to obtain an adequate idea of the ureteral outline.

Attempts have been made to visualize accurately the ureter by various methods. Compression bags placed over the lower part of the ureter a few minutes prior to exposure have often proved to be of some assistance. It is advisable to have the patient placed first in the Trendelenburg position and later in order to visualize the lower part of the ureter, to have him sit up with the legs flat on the table for five or ten minutes prior to the second or last film. In the later films the lower end of the ureter is sometimes visualized, apparently because of stasis resulting from filling of the bladder. It is surprising how often marked ureterectasis can be overlooked entirely in the excretory ureterogram and it may be necessary to resort to retrograde ureterography with the aid of multiple or bulb catheters.

Excretory urography is frequently disappointing in the identification of suspected shadows in the area of the ureter (fig 5). Unless there are actual obstruction and retention of urine in the ureter at the time of exposure there may be no evidence of ureterectasis and even complete failure of visualization of the ureteral outline. When the shadow is in the lower end of the ureter the bladder should be emptied before the last films are taken, otherwise the vesical outline will completely overshadow the outline of the adjacent ureter.

Excretory urography should be of great value in determining the existence of actual stricture of the ureter which a few years ago was thought to be of such frequent occurrence. Excretory urography will visualize ureterectasis, which must be present if actual stricture is present. There may be some difficulty in distinguishing between atonic and obstructive dilatation, but as a rule the localized area of constriction, with ureterectasis immediately above it, will identify actual obstruction. If an excretory urogram was made as a routine in cases in which stricture of the ureter was suspected only few patients would be subjected to ureteral dilation by the conscientious urologist.

Similarly, many so-called kinks in the ureter, which formerly have been given a far more important place by urologists than they merited, have disappeared in repeated excretory urograms. It is evident that such angulations were often caused by spasm secondary to irritation by a catheter. Other apparent kinks exist temporarily as the result of postural, respiratory or other physiologic and anatomic conditions. When ureteral angulation persists in the excretory urogram and in spite of postural change and is accompanied by urographic evidence of stasis, it may be regarded as of pathologic significance. It is of interest that ureteral spasm at the ureteropelvic juncture which often accompanies renal stone will many times be visible in the excretory urogram.

The excretory ureterogram may also be of great value in determining the postoperative condition of the ureter. It offers a simple method of determining the

existence of injury to the ureter after operations on the female pelvic organs. It may be the only method of ascertaining the functional results or complications following transplantation of the ureters into the sigmoid.

EXCRETORY CYSTOGRAPHY

The bladder frequently will be visualized coincidentally in the late films made in the course of excretory urography. These data, which are available as a by-product, are frequently of considerable clinical use. A coincident vesical neoplasm, diverticulum or other deformity is often visualized, which might otherwise have been overlooked. Although the bladder is not always completely filled, enough evidence of deformity when present, is usually seen to permit of diagnosis. With failure of visualization of the upper part of the urinary tract because of intestinal flatus, poor preparation, roentgenologic technic or physiologic or anatomic circumstances, the presence of the excreted medium in the bladder may be the only evidence available of adequate renal function. The excretory urogram may also be of value in making an approximate estimate of the amount of residual urine in the bladder when it is impossible or inadvisable to employ a urethral catheter.

SUMMARY AND CONCLUSIONS

Although the foregoing data are so condensed that they constitute but a summary of the information available by means of excretory urography, nevertheless the following may be emphasized:

1 Excretory urography should be and will be employed as a routine in the diagnosis of abdominal lesions.

2 Its greatest handicap is interpretation, which will be so standardized as to permit the method to be more generally employed.

3 Its greatest value will be in determining the presence of stasis in the renal pelvis or ureter and in interpretation of shadows in the upper part of the urinary tract, and giving fairly accurate estimates of renal function.

4 Excretory urography will also be used to a less extent in the recognition of renal tumor, tuberculosis and anomaly.

5 It will always be an invaluable aid to the urologist in conditions in which cystoscopy and ureteral catheterization are impossible or inadvisable.

6 It should be of much help in determining the presence or, rather, the absence of stricture of the ureter.

7 It should also be of great help in determining the necessity for the surgical treatment of renal ptosis.

8 The data that it gives should be complementary to other urologic data and in only a limited field will it entirely replace them.

Possibilities to Unassisted Eyes—Our final opinion of course in any case is based upon a compounding of sense data and an analysis by the mind of all the information we have collected by all the means at our disposal. The more accurately however we observe with our special senses the more judicious will our choice of other methods be and the more accurate the final opinion. Do not think that the few illustrations I have given you are intended to do more than indicate the range of possibilities open to your unassisted eyes, hands, ears and nostrils. Your daily life in clinical medicine will furnish you with others in plenty, some which are old and familiar and others which you will reveal to yourselves.—Ryle, J. A. *The Training and Use of the Senses in Clinical Work*. *Gen. Hosp. Gaz.* 47:421 (Oct. 28) 1933.

EXCRETION UROGRAPHY

WITH PARTICULAR REFERENCE TO A NEWLY DEVELOPED COMPOUND SODIUM ORTHO-iodohippurate

MOSES SWICK, MD
NEW YORK

This paper embodies the results of endeavors to overcome certain disadvantages that have evidenced themselves since my original contribution¹ to excretion urography with iopax. For example, the volume administered was inconvenient, the dose large, the expense great, and the substance as such not representative of a product of normal metabolism.

The underlying principle of the present investigations concerns itself with the utilization of a normal product of metabolism as an organic nucleus for combination with the radiopaque element necessary for the visualization of the urinary tract. The substance I now propose is sodium ortho-iodohippurate, a halogen derivative of a compound normally found in the human urine.

In order to comprehend clearly the rationale for the development of this substance, the following considerations are worthy of note:

1 It has been known for a long time that the introduction of benzoic acid or its sodium salt into the

Fig 1—Structural formula for iodohippuric acid

animal organism results in its conjugation with glycine and in the excretion of the corresponding hippuric acid derivative. Similarly, it has been demonstrated that iodohippuric acid is excreted into the urine of the dog and the rabbit after the administration of iodobenzoic acid.

2 Animal experimentation has shown that the elimination of hippuric acid after benzoic acid administration represents the end-result of processes of detoxification.

3 As an organic parent-substance for combination with iodine or bromine, sodium hippurate appeared suitable since it is very soluble in water, is neutral in solution, is a normal metabolite and product of detoxification, is well tolerated, and is quantitatively excreted in the urine of the rabbit.

In the light of these observations it was felt that sodium ortho-iodohippurate should meet the necessary requisites for excretion urography.

On the basis of its use in more than 200 cases I have found the substance to be nontoxic, highly soluble and

neutral in solution, and to yield satisfactory urograms. It possesses 38.8 per cent of iodine in stable organic union. Iodism has never been observed. Generalized warmth and occasionally nausea and vomiting of very transient duration have been the only reactions noted. Thrombosis at the site of injection has not been observed. The compound is well tolerated and may be recovered from the urine as the insoluble acid. Rabbits were found to tolerate from 2 to 2.5 Gm of substance per kilogram of body weight, administered intravenously in approximately 30 per cent concentration over a period of about ten minutes. Normally, from 90 to 95 per cent is excreted within eight hours after injection, from 60 to 66 per cent during the first hour, and from 70 to 80 per cent during the first two hours. A solution of this substance remains unchanged in color or reaction after sterilization or on standing and may be prepared and distributed in sterile vials ready for use.

Fig 2—Structural formula for sodium ortho-iodohippurate

DOSAGE AND TECHNIC

For adults, a dose between 10 and 15 Gm of substance dissolved in distilled water in approximately 50 per cent concentration has been used. The injection should take about five minutes, the first exposure made about ten minutes later and two subsequent ones at twenty minute intervals. In cases of functional derangements, particularly in the presence of obstructive conditions, additional films are indicated to determine definitely the absence of visualization or the presence of late visualization. Children under 13 years of age have received 10 Gm doses without ill effects, occasionally the injection in the latter is associated with transitory nausea and vomiting.

Fig 3—Curves of excretion

10 Gm Dose			15 Gm Dose		
Hours	Iodine	Volume	Hours	Iodine	Volume
2	2.120 Gm	202 cc	2	2.517 Gm	160 cc
4	0.340 Gm	220 cc	4	0.110 Gm	100 cc
6	0.099 Gm	220 cc	6	0.100 Gm	20 cc

The oral administration in man has also yielded satisfactory results. Of twenty-five cases approximately 50 per cent showed good diagnostic urograms from ninety to 135 minutes after administration. From 10 to 15 Gm of the substance dissolved in approximately 75 cc of simple syrup was given by mouth. No reac-

This work was carried out with the aid of a grant from the Emanuel 1st Fellowship Fund.

Urol. 15, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

tions were ever noted. The only subjective sensation recorded is the salty aromatic taste of the solution. Forty-five minutes after the intake of the solution, the patient is placed on the x-ray table, a moderate degree of compression is applied, and exposures are made sixty, ninety, 120 and 150 minutes after the ingestion of the substance. Further investigations with the oral

urate degree of compression over the region of the urinary bladder by means of an air-inflated balloon held in place by the canvas sheet of the compressing apparatus. The balloon is applied in the midline, just above the symphysis pubis, immediately after the completion of the injection, and is maintained without disturbance for the entire period of the three exposures. It is felt that an artificial dilation of the urinary tract with the aid of compression is not produced when normal tonic conditions prevail.

Further studies with related substances and with the administration of the mono-iodobenzoate and diiodobenzoate of sodium in conjunction with glycine by the intravenous and oral routes are being continued.

GENERAL CONSIDERATIONS

Excretion urography should be viewed only as one of the aids in urologic diagnosis and as such not without its limitations. This method cannot entirely supplant cystoscopy or retrograde pyelography, and it must be considered in conjunction with other means of inves-

Fig 4—Intravenous urogram. Bilateral renal calculi with very little effect on the pelvis and calices. The left pelvis and calices are larger than those on the right side.

administration are in progress. At the present time it is my opinion that the results by the oral route will not be as consistently good as those given intravenously.

Fig 5—Intravenous urogram. Left hydronephrotic dystopic nonrotated kidney with calculus in its lower pole, right double pelvis, double ureter with dilatation of the lower half. The chief complaint was a tender mass to the left of the umbilicus and hematuria.

PREPARATION OF THE PATIENT

The patient is prepared as for any roentgen urinary examination: castor oil the night before, no fluids during the night, and nothing by mouth in the morning.

IMPORTANCE OF COMPRESSION

Of importance in obtaining clearly defined and readable excretory urograms is the application of a mod-

Fig 6—Oral urogram showing normal urinary tracts. Iodized poppy seed oil seen in the bony pelvis is the result of injection of a fistulous tract.

eration in each individual case. When doubt exists, cystoscopy and retrograde pyelography should be employed. The latter procedures too, despite their years of existence, are not always fool proof. The following example is illustrative.

A patient with a history of bilateral renal pain associated with hematuria was found on cystoscopy, to have good indigo carmine excretion from both sides, 20 cc retention in the left kidney pelvis, but none in the right, as determined by aspiration through the catheter, which was thought to be in the pelvis. Accordingly, a left retrograde pyelogram—the side with retention—was made, abnormality of the right urinary tract not being expected. But the intravenous urogram visualized a hydronephrosis of the right renal pelvis, the slight dilatation of the left renal pelvis resembling that seen by the retrograde route, was found to be incidental to a stone in its lower ureter.

Because the mechanism of this type of urographic visualization is based on excretion, one should think in terms of renal function as it pertains to this method.

From studies of excretion, it is observed that the normally functioning kidney possesses the ability to excrete urographic substances in high concentration within a short period. This may be characterized as the thrust-excretion ability of the normally functioning kidney. It is obvious that, in the case of a poorly or nonfunctioning kidney, when the concentrating power is impaired, poor or no visualization will be found, since a certain concentration of the radiopaque element is necessary for roentgenologic visualization. Broadly speaking, then, it may be stated that visualization, poor visualization or no visualization is dependent on renal and extrarenal factors. When, however, the additional mechanism of obstruction is present (reservoir mechanism) visualization may be had, although the height of excretion requisite under normal circumstances is absent, provided excretion takes place. Thus, in some cases of hydronephrosis, despite the presence of comparatively little intact renal tissue, good visualization may still be encountered. This brings up an important consideration, namely, in cases of hydronephrosis, the presence of functioning renal tissue, as evidenced by the radiologic observations, is no quantitative criterion nor one for determining the type of therapeutic procedure. The latter will depend on the individual case and the pathologic anatomic status, as well as on the particular approach of the physician or surgeon to the case in question.

Further, it is important to point out that the functional activity of the kidney may be temporarily inhibited and that the mere nonvisualization of the urinary tract at a given examination does not necessarily signify permanent renal damage.

Fig. 7—Oral urogram in a patient with congenitally absent left kidney, complicated originally by a ureteral stone who was operated on the operation followed by a stricture and ulceration of the ureter by a recurrent stone. Finally a permanent lumbar uretero-tomy was performed. The urogram shows dilation of the calices pelvis and upper ureteral stump. A calculus is seen situated in the region of that stump.

On the other hand it should also be stressed that the mere nonvisualization of the upper urinary tract incidental to the functional anatomic derangement of the kidney parenchyma may in itself be of great assistance as a means of localization of the disease and in diagnosis when considered together with other clinical data.

Cases of calculous pyonephrosis, tuberculous pyonephrosis, infected hydronephrosis and tumors of the kidney have been so diagnosed with great regularity when viewed clinically in their entirety. In addition, one gains an insight into the functional and anatomic status of the contralateral side, so essential in the evaluation of the individual as an operative risk.

Fig. 8—Trapped right hydronephrotic kidney due to aberrant vessels at the ureteropelvic junction. Ureter not visualized. Cystoscopic examination failed to detect this abnormality. The left urinary tract is somewhat dilated as a result of a ureteral stone overlying the sacrum.

In passing, attention should be called to instances of failure of visualization or poor visualization in the presence of good renal function, as determined by indigo carmine excretion, these cases are difficult to explain.

In the various aspects pertaining to the question of renal function and roentgenologic visualization, it should be emphasized that this method is excretory in nature and that one should therefore constantly bear in mind the processes taking place in both the renal and extrarenal systems.

A familiarity with the indications and contraindications for excretion urography possessed by most medical men makes it unnecessary to deal with these aspects.

CONCLUSIONS

Excretion urography has been found useful in many of the cases in which retrograde pyelography was in general indicated and in which the latter, in the presence of mechanical difficulties or infections, could not be executed, and vice versa retrograde pyelography is considered essential in corroborating or supplementing when the results with excretion urography are equivocal.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. BRAASCH AND SWICK

DR. IRA R. SISK, Madison Wis.: I agree with Dr. Braasch's general statement regarding the application of this method in general diagnosis. That its greatest field of usefulness is in the diagnosis of obstructive lesions and stones cannot be denied. As he said many cases of tuberculosis and of polycystic kidney can be recognized by this method alone. It has been my observation

that the greatest source of error is from reading into the film more than can really be seen, also from attempting diagnosis from excretory urography alone when there is pus in the urine and inflammatory disease somewhere in the urinary tract for which cystoscopy should also be used. Another source of error is in the cases of hematuria when normal kidney pelvis and ureters are found but lesions exist elsewhere in the urinary tract. Dr Braasch did not mention this method of diagnosis in children. In the clinic with which I am connected we use intravenous urography in a larger percentage of children than of adults. It is quite reliable in the diagnosis of tumors of the kidney in children and in determining the presence of anomalies or other conditions that may impede the progress in the ordinary pyelitis of childhood. Dr Braasch did not have time to read one portion of his paper which dealt with genito-urinary surgery. In determining the results in conservative operations on the renal pelvis and following transplantation of the ureters to the sigmoid, it is invaluable. Also much valuable information may be obtained from the procedure when used before the second ureter is transplanted regarding the function and the drainage on the side on which the operation has already been performed. Dr Swick's contribution is valuable. The advantage of a substance which, after oral administration, will give the pictures he has demonstrated is too evident to need discussion. Although he states that it is successful in only about 50 per cent of cases, he will with further work, I am sure, be able to develop the substance to a point at which it will be as valuable as intravenous urography is today.

DR L. T. LEWALD, New York. Dr Braasch and Dr Swick have added a great deal to the subject of excretion urography, a method which has now passed the experimental stage and points the way to a brilliant future not only in urologic work but also in general medicine. The surface apparently has only been scratched in regard to the use by the internist of this method of estimating kidney function and diagnosis of renal disease. I have been somewhat disappointed by the apparent lack of interest on the part of the internist in the use of this method of diagnosis in connection with the diagnosis of nephritis. I trust that Dr Swick's latest efforts to render the method applicable to office practice by means of the oral administration of sodium iodohippurate will stimulate internists and

also be possible to study the size and function of the kidneys (arteriosclerotic kidney). I do not know of any series of cases studied from this standpoint but hope to be able to carry out such a series in the near future. Dr Swick's statement that sodium iodohippurate may be safely used in children would make it possible to carry out a series of observations in connection with my service as roentgenologist at Willard Parker Hospital in a series of postscarlatinal cases, in an effort to

Fig. 10—Later exposure of case shown in figure 9 showing the complete filling of the left infected hydronephrotic kidney. These two illustrations demonstrate the comparatively good visualization that may be encountered in some cases of hydronephrosis despite the mere presence of comparatively little intact renal tissue. Therefore in cases of hydronephrosis the presence of functioning renal tissue as evidenced by the radiologic changes is no quantitative criterion nor one for determining the type of therapeutic procedure.

determine the effect of the disease on the kidney. It would also appear possible to test out various diuretics taken in conjunction with excretion urography.

DR THOMAS D. MOORE, Memphis, Tenn. Dr Braasch mentioned the difficulty of interpreting urograms that lack definition. Three simple measures have been found worth while as a means of improving density and detail. 1. If the examination is to be made in the morning, a preliminary laxative is given the evening before. 2. A state of partial dehydration is induced by withholding fluids during the twelve hour period. 3. The use of localized compression immediately above the symphysis pubis by placing a small rubber ball beneath the compression binder has been found more effective than the large inflatable bag commonly used for the purpose. The small ball is removed during the actual exposure of the films, permitting the lower ureters to fill and eliminating the shadow of the ball.

DR W. F. BRAASCH, Rochester, Minn. To return to the subject of terminology, it should be stated that the term "excretion urography" cannot be used, since excretion is a noun. Therefore the term "excretory urography" will most accurately describe the procedure and will probably be permanent. The term intravenous urography probably will soon disappear entirely since the substance for oral administration which Dr Swick has recently discovered will doubtless supplant present methods of intravenous injection. Excretory cystography may be of value in calling attention to diverticula of the bladder or some other deformity in the vesical outline that might not be suggested by the clinical data at hand. It should be studied as a routine in every excretory urogram. If it is inadvisable to catheterize a patient, excretory urography may be used to demonstrate the presence of residual urine.

DR MOSES SWICK, New York. A case that demonstrated discrepancies between urographic observations and the real clinical condition recently came under my observation. The patient was a female in whom cystoscopy showed normal ureters. Catheters were passed up both sides and no obstruction

Fig. 9—Intravenous urogram in a 6 year old child admitted for pyuria showing a dilated right urinary tract with angulation of the ureter. The left kidney shows filling of three dilated calices. Its ureter is not visualized. See figure 10.

roentgenologists to greater effort in this respect. From my former experience as a pathologist it would seem possible not only to differentiate certain anomalies of the kidney, such as absence of one kidney or the presence of a horseshoe kidney or a double ureter but also to determine the size of each kidney and differentiate such conditions as chronic interstitial nephritis (small granular kidney). In cardiovascular disease it should

was encountered. A pvelogram showed no cupping. Several days later, cystoscopy was performed again and a normal pvelogram was made, but this time it showed dilatation and clubbing of the calices on one side. A few days later cystoscopy was done and this time the pvelogram showed clubbing on both sides. Two years later the patient showed eveground changes and evidences of uremia. In other words, this patient had from the beginning a pvelonephritis, which was not recognizable by the investigations made and the disease went on to the stage of typical contracted kidney.

INTERPRETATION OF CHEST ROENTGENOGRAMS

KENNON DUNHAM, M.D.
CINCINNATI

For more than twenty years the laboratory with which I am associated (as many other laboratories) has studied necropsy material to determine the relation between x-ray densities and pathologic observations. It is my opinion that the relative degrees of scar tissue and pulmonary exudate can be determined from a study of x-ray films with sufficient accuracy to be of great practical value in the diagnosis, prognosis and treatment of pulmonary tuberculosis.

Pulmonary tuberculosis can be understood more easily if the various lesions are regarded as the products of inflammation and if it is remembered that tuberculous infection varies from marked chronicity to

The study of a case of pulmonary tuberculosis necessitates determining not only the extent and location of the lesions but also the relative amounts of scar tissue (repair, suggesting resistance) and of the pulmonary exudate (acute inflammation). Great consideration must be given, not only as to whether a cavity has formed, but also as to whether an abscess, which causes

Fig 2—Exudative or pneumonic type tuberculosis due to pulmonary exudate in upper right lobe. Very virulent inflammation. Cavity breaking down. Lower lobe and part of upper lobe illustrates caseous bronchopneumonia due to aspiration. Bronchogenic spread.

Fig 1—Fan (below clavicle) illustrating lobular pneumonia found in adult apical tubercle. Stereoscopically this is seen coming to the back and not to the anterior part of the chest.

severe activity. Thus the densities as shown on the x-ray film reveal lesions that vary from dense scar tissue (proliferative type) to extensive pulmonary exudate (exudative type).

a cavity, will probably develop. Inflammation with repair or degeneration, due to tuberculous infection, exists just as it does following other infections. Thus, pulmonary tuberculosis may manifest itself as lobar pneumonia, lobular pneumonia or bronchopneumonia. Such lesions occur in patients who have had sufficient previous tuberculous infection to produce a state of allergy in the individual. Miliary tuberculosis as described in textbooks, not the miliary tuberculosis of Laënnec, probably develops when allergy does not exist or when it is not sufficiently active to permit the tubercle bacillus to cause an inflammatory reaction and produce exudate. But this is another story.

Adult apical and subapical tuberculosis, also called nodose and fibroid tuberculosis, starts as a lobular pneumonia and, as Birch-Hirschfeld showed in 1898, most commonly develops in the posterior apical bronchus. This should not be described as below the clavicle because that indicates the anterior part of the chest. This type of lesion has been described as the fan, because it was first visualized as such on the x-ray plate. It is a localized area of pulmonary inflammation with pulmonary exudate, which may repair or break down (a lobular pneumonia). At a later date other similar lesions may develop and then there are two or more areas of lobular pneumonia in different inflammatory stages. These show different densities on the x-ray film. To differentiate these densities and to determine the extent and degree of repair or degeneration of the lesions necessitates excellent stereoscopic films.

Caseous bronchopneumonia usually follows when the lobular pneumonias break down and liberate nascent tubercle bacilli. This is often spoken of as the bronchogenic spread and is due to the aspiration of infectious dioplets into good lung tissue. It commonly follows a hemorrhage when the sputum is positive. This lesion is portrayed on the x-ray plate as fine, coarse, or flocculent mottling (indicating varying degrees of the vicious-

Fig 3—Fibroid tuberculosis—the proliferative type due to connective tissue in lobe illustrates great chronicity

ness of the infection) associated with extensive and usually old lesions in the upper lobes.

Tuberculous lobar pneumonia is not as prevalent as tuberculous lobular pneumonia but is a common lesion. It has been written of as basal tuberculosis and I have written of it as basal tuberculosis but have been sufficiently Irish to describe basal tuberculosis in an upper lobe. It is more common in Negroes and children than in white adults. It is a very vicious tuberculous inflammation and few survive it. It usually cavitates, and the lung should be collapsed as soon as the diagnosis is confirmed by the presence of positive sputum. The entire lobe is seldom involved at the start but it has a nasty way of spreading even before positive sputum is obtained. Frequently, exudate will absorb in one part of the lobe and a cavity form in another part of the same lobe.

Two types of x-ray densities in tuberculous pneumonia are to be noted. One patient will have the even density of a heavy pneumonia and another the mottling of bronchopneumonia. These cases showing the mottling of bronchopneumonia do not have the upper lobe lesion from which to aspirate infectious droplets. Positive sputum is found comparatively late in either tuberculous pneumonia or the basal type of tuberculosis simulating bronchopneumonia. The x-ray density is not characteristic as it is in the fan type. A diagnosis may be suspected but not made from the films alone. Malignancy as well as any pulmonary exudate may simulate the densities of tuberculous lobar pneumonia (basal tuberculosis).

The difference between lobular tuberculosis and tuberculous lobar pneumonia is probably due only to the severity of the infection. The virulence of the germ, the size and frequency of the dose and the resistance of the body each plays its unknown part.

Lobular tuberculosis, a localized inflammation, more frequently repairs and lays down scar tissue and is often spoken of as fibroid tuberculosis. Thus it is all important to distinguish between scar tissue and pulmonary exudate. If the exudate is spreading, one may expect that an abscess will develop and a cavity form. If the exudate is not spreading, one may expect that scar tissue is being laid down and that absorption is taking place. This is determined by a series of films taken over a few months and answers the question as to whether pneumothorax or other collapse therapy is indicated.

Pulmonary exudate, due to whatever cause, requires rest in bed until quiescent, and medical supervision much longer. To determine the degree of pulmonary exudate and fibrosis, the best x-ray plates are not good enough. Stereoscopic plates are a necessity. There has been much discussion as to which are the best exposures for x-ray chest films. I would answer that question by saying that the best exposure is that which will show best and most accurately the anatomy of the lung, without contrast mediums. The film that will show the trachea, the right and left bronchus, the pulmonary arteries and the trunks to the five lobes will do, and such an exposure will not destroy the picture of the

Fig 4—Tuberculous pneumonia in upper right lobe. Sputum is positive. This the author sometimes refers to as basal tuberculosis in an upper lobe. Such cases will break down very soon after this condition develops. Abscesses are forming and a cavity must follow.

fine exudate for which one is looking. It will prevent mistaking exudate for scar tissue (fibrosis).

When exudate is absorbing and scar tissue is developing, the patient is improving, and it is all important that the proper deduction be made. The care of the patient depends on it.

The only treatment of tuberculosis is to assist repair and prevent degeneration as far as is possible.

ABSTRACT OF DISCUSSION

DR HENRY K. PANCOAST, Philadelphia. Dr Dunham was I believe the first in this country to teach roentgenologists how to diagnose pulmonary tuberculosis correctly, and that was because he taught that it must be diagnosed on the basis of the actual pathologic process that is present. What he has shown is an interpretation of pathologic processes that are present. It is surprising in how many instances this teaching has not been realized and in how many instances those who are attempting to diagnose tuberculosis do not realize that there are definite criteria for correct interpretation: (1) a knowledge of the anatomy of the lung, (2) a knowledge of the appearance of the lung in the roentgenogram within normal limits, (3) a knowledge of the pathology of tuberculosis, (4) how that pathologic condition appears in the roentgenogram, and (5) the

Fig. 5.—Basal tuberculosis in a Negro with positive sputum. This is the bronchial pneumonic variety in contrast to the homogeneous density of the pneumonic type. Such a film might be produced by carcinoma. Tuberculosis should never be read from the film alone in such a case.

correct technique of the examination. Every one of those factors is absolutely essential to a correct diagnosis. One must show the shadows that are the most difficult to bring out: those of the exudate. One must have stereoscopic films at least to make the original diagnosis because the single film contains the shadows of all structures all the way through the chest cast in one flat plane. Those lesions or structures which are farthest away from the film will be almost invisible in some instances because they are spread out over such a wide film area. The stereoscope brings everything back to the place at which it belongs and shows which structure or which lesion casts the shadows. It is customary to regard lobular pneumonic areas in the apical portion of the upper lobe as tuberculous in origin in practically all instances. Such appearances are not all tuberculous, however, because other infections may produce the same appearances. They have the same appearance as that of tuberculous exudate but they disappear in a week or ten days. I never think of making a final diagnosis of pulmonary tuberculosis in many cases seen for the first time when such exudative shadows are found in the upper lobe but I insist that the patient be examined again in a period of possibly three weeks in order to make certain that the individual does not have some other infection. It is surprising how many times the shadows will disappear.

DR H. KENNON DUNHAM, Cincinnati. When these fans or lobes of different densities appear showing infection that have occurred at different times and in different stages

of repair or degeneration, one is quite safe in making a diagnosis of pulmonary tuberculosis. When a pneumonic-like area of one density appears, one cannot accurately deduce the etiologic factor. I have presented two illustrations of cases coming to autopsy to show the importance of not diagnosing tuberculous pneumonia from one density. By studying these chests over months, one can determine whether pulmonary exudate is extending and therefore that the patient is worse, or whether pulmonary exudate is arrested or is disappearing by absorption, and the patient is better. Putting it in another way, when the X-ray film does not show the pulmonary lesion advancing, the patient is improving, but in the pneumonic type there may be absorption of exudate in one part and a cavity developing in another part of the same lobe, also a lesion on one side may be getting much better and a new and nasty lesion developing on the opposite side. It is all important to study X-ray films to determine the relation between pulmonary exudate and scar tissue development and to realize the terror of these basal (pneumonic) types of tuberculosis, which seldom fully recover. In this way the roentgenologist can best help the clinician by determining the need of additional rest or collapse therapy.

LEUKEMIC RETICULO-ENDOTHELIOSIS
(MONOCYTIC LEUKEMIA)

WITH REPORT OF CASES

ALVIN G. FOORD, M.D.

PASADENA, CALIF.

LAWRENCE PARSONS, M.D.

AND

E. M. BUTT, M.D.

LOS ANGELES

More or less generalized involvement of the reticulo-endothelial system is found in various pathologic conditions, which can be fairly well grouped under the following headings:

- 1 Storage histiocytomatosis—Gaucher's disease, Pick-Niemann disease, xanthomatosis and sometimes, diabetic lipemia
- 2 Granulomatosis—Hodgkin's disease
- 3 Hyperplasia—reticulo endotheliosis
 - (A) Leukemic reticulo endotheliosis (monocytic or histiocytic leukemia) with or without blastoma formation
 - (B) Ateleukemic reticulo endotheliosis with or without blastoma formation—response to infection (?) or true systemic disease (?)
- 4 Tumors—reticulum cell lymphosarcoma

The conditions classified under 1, 2 and 4 are fairly well defined, but considerable discussion has arisen concerning reticulo-endotheliosis. The pathologic changes in the cases described are nearly uniformly constant and consist chiefly of a diffuse proliferation primarily of the reticulum cells and sometimes of the endothelial cells in the hematopoietic system, chiefly in the spleen and lymph nodes, and in most of the other viscera. Some investigators, notably Sternberg maintain that the condition is merely an atypical response to infection. Sternberg considers all acute leukemias in the same category. However, most writers consider the cases with an increased number of cells of the monocytic series associated with diffuse growth of the reticulo-endothelial cells in the tissues as cases of monocytic leukemia comparable in all respects to the more usual myeloid and lymphatic leukemias. Reschard and

From the Laboratories of the Pasadena Hospital, Pasadena, Calif., and the Los Angeles County General Hospital, Los Angeles.
Read before the Section on Pathology and Bacteriology at the Eighty-Fifth Annual Session of the American Medical Association, Milwaukee, June 14, 1935.

Schilling-Torgau¹ reported the first case of this type in 1913, and Rosenthal² the first in America in 1921. Dameshek,³ in his comprehensive review of the subject in 1930, listed eighteen proved cases, and Clough⁴ in 1932, gave a complete summary of twenty-three cases, including one of his own. Gittins and Hawksley,⁵ Farrar and Cameron,⁶ Rinehart,⁷ Rucks and Cunningham,⁸ Cooke,⁹ Gardner,¹⁰ Sydenstricker and Phinzy¹¹ and Bohne and Huismans¹² each reported one case, and Osgood and Lyght¹³ two cases, checked hematologically and by postmortem histologic studies by Bunting, making a total of thirty-three cases in all. Autopsies were made in twenty-one cases of this group.

Clinically, most of the cases described have run a clinical course similar to other acute leukemias, lasting from two weeks to a few months. Infection of the mouth or throat and spontaneous purpura are the rule, especially late in the disease. Rapidly progressive anemia and moderate fever are practically constant features. Palpable swelling of the spleen, liver and lymph nodes is more often present than not. Examination of the blood as a rule shows a marked or moderate decrease in red cells and hemoglobin, the white cell counts averaging from about 15,000 to 50,000, however, two cases have shown more than 400,000 cells (Swirschewskaja¹⁴ and Lawrence and his associates¹⁵). The monocytic cells usually form from about 50 to 75 per cent of the total count, sometimes more. The type cell described by all the authors is seldom a mature monocyte, but usually its immediate precursors, including the most immature cell, or histiocyte (Dameshek³). These cells are larger than any normal blood cells and in moist preparations show marked motility, and in supravital preparations, active ingestion of dye. In preparations stained according to the Wright and Giemsa methods pseudopodia or scalloping of the edges testifies to the motility of the cells. The cytoplasm closely resembles that of a mature monocyte, being blue-gray and of ground-glass appearance, with typical fine monocytic granules which are first seen about the nucleus in the youngest cells. The nucleus is large, oval, indented, bean-shaped or even almost lobed. The chromatin is arranged in a very fine spongelike meshwork which becomes more coarse and skelelike in more mature cells. Phagocytes containing red cells and cellular fragments have been reported by a few authors, especially Clough⁴. Nearly all authors report that the

immature cells are oxidase-negative, although Farley,¹⁶ and Lawrence and his co-workers¹⁷ found the cells to be positive.

Post mortem, necrotizing lesions in the mouth or the throat are usually found, and constantly the lymph nodes, spleen and liver are enlarged. Usually the bone marrow is hyperplastic. Evidences of hemorrhages in the skin and serous surfaces are nearly always found. The kidneys are swollen, owing to the growth of reticuloendothelial cells and degenerative tubular changes. Rarely, organizing fibrinous exudate is seen on the pericardium (Gardner¹⁰ and Lawrence and his associates¹⁵), or even on the pleura (Gardner¹⁰).

Histologically, the architecture of the lymph nodes and spleen is obliterated by a marked proliferation of reticular cells, periportal growth is seen in the liver, and proliferation of reticular cells is found in the kidneys, the serosal surfaces, and the perivascular stroma of nearly all the organs, especially the suprarenal glands, thymus, pancreas and gastro-intestinal tract. The bone marrow usually shows a diffuse or patchy involvement. Thorough study of the reticulum in between the newly formed cells has not been made in any of the recent leukemic cases in the literature, although in an aleukemic case, Tschistowitsch and Bykowa¹⁷ showed clearly a marked proliferation of a fine meshwork of reticulum to which the cells were intimately connected. In most cases there was little evidence of proliferation of the endothelium. However, Bock and Wiede¹⁸ described proliferation of the endothelium of the lymph nodes, the splenic sinuses and the Kupffer cells, with transitions from swollen cells to completely loosened leukemic cells. Swirschewskaja¹⁴ found the same changes in the splenic sinuses.

Myeloid hyperplasia of slight degree, in the spleen especially, has been found in a few cases, including those of Schilling,¹ Vyshegorodtzeff¹⁹ Ugrumow,²⁰ Fleischmann²¹ and Bingel.²²

Of particular interest is a case reported by Gittins and Hawksley.⁵ A child, aged 1 year, showed a typical blood picture and had diffuse reticulosis and bilateral large tumors in the ovaries, each of which weighed 210 Gm., and were composed of cells identical with those in the other tissues. Such a case speaks against the inflammatory infectious origin of monocytic leukemia but simulates more nearly cases of myelogenous leukemia with secondary blastomatous growths, as classically seen in chloroma.

Cases of leukemia showing immature granulocytes and monocytic or monocyte-like cells in the blood stream have always led to confusion in classification and to arguments as to the origin of the monocytes. Anagnostou²³ considered the cells in dispute in his case to be monocytoïd promyelocytes (oxidase-negative). Hittmair²⁴ described a case showing myeloid leukemia on postmortem histologic examination in which 42.8 per

cent monocytoïd cells were found in the blood along with many myeloblasts and promyelocytes. He expressed the belief that these monocytoïd cells are developed from myeloblasts. Bykova²⁵ believed in a similar origin for the monocytes in his case 2, as did Reich⁶ in his case.

Likewise, there is no unanimity of opinion concerning the classification of aleukemic cases of reticulo-endotheliosis, in which the postmortem changes are quite similar to those in the leukemic type. Clinically, most of the cases reported have shown anemia, hemorrhagic diatheses, fever, enlargement of the nodes, spleen and liver, and oftentimes necroses in the mouth or the throat. Tschistowitsch and Bykova¹⁷ and Feller and Risak²⁷ considered their cases to be true aleukemic states similar to so-called aleukemic leukemia of other varieties. Akiba²⁸, Terplan,²⁹ Letterer³⁰ and Krahn³¹ however, expressed the belief that the condition is one of bizarre response to infection. At the present time the question as to the true state of affairs cannot be answered. In only one case, that reported by Feller and Risak,²⁷ were immature monocytes found in the aleukemic blood. The finding of tumor-like nodules in the spleen, skin, esophagus, gallbladder and epicardium in the case reported by Lasowsky³² is more in keeping with a leukemic process than with infection. Goldzieher's³³ case with marked involvement of the bone marrow and the bone substance also favors this view.

REPORT OF CASES

CASE 1—F. P., a white schoolboy, aged 17, was admitted to the Pasadena Hospital on Feb 9, 1932, in the service of Dr Duncan Parham, with an ulcerative lesion around his right lower second molar, gingivitis, rather marked anemia, malaise and generalized swelling of the lymph nodes.

About four weeks before admission he said that he felt lymph nodes in his left axilla, but claimed that he was perfectly well until an infection of the gums developed one week later, which he claimed was due to the breaking off of a wooden toothpick between the gum and the molar. The infection spread to

On a few occasions his temperature was slightly elevated. During the week before admission his gums had swollen markedly and had become markedly thickened and reddened. General enlargement of the lymph nodes had developed in all the superficial groups. He had no evidence of bleeding either in the skin or in the mucosae, but rather marked anemia developed. His appetite had been very poor, and he had lost considerable weight.

On examination, a foul-smelling, necrotic lesion about 2 cm in diameter was found about the second right lower molar, and marked swelling, reddening and thickening of the rest of the gums were present. Marked generalized enlargement of the lymph nodes was present. The spleen was half-way from the

Fig 1 (case 1)—Immature monocytes in blood smear one showing mitosis

ribs to the umbilicus, and the liver was three fingerbreadths below the costal margin. The heart and lungs were normal. The temperature varied from 100 to 102 F, the pulse rate from 100 to 110, and the respiratory rate, from 20 to 25. He continued to go downhill during his stay in the hospital. During the last week of life the nodes decreased moderately in size and the spleen shrank somewhat, but was still two fingerbreadths below the ribs. The ulceration in the mouth extended to the throat, there was marked edema of the peritonsillar areas and palate, and marked difficulty in respiration resulted. During the last few days of life, petechial hemorrhages were found in the skin chiefly of the chest, and on the last day moderate jaundice appeared. Death occurred apparently from exhaustion and bronchopneumonia on Feb 27, 1932. A clinical diagnosis of leukemic reticulo-endotheliosis was made on the clinical and laboratory evidence.

Laboratory examinations showed several specimens of urine to be concentrated and to contain 2 plus albumin and large numbers of granular and renal epithelial cell casts. Smears from the ulcer in the gum showed many Vincent spirochetes and fusiform bacilli, staphylococci, streptococci and other bacteria found in the mouth. Aerobic cultures yielded chiefly *Staphylococcus aureus-hemolyticus* and *Streptococcus hemolyticus* beta. Two blood cultures were negative. The Wassermann and Kahn tests were negative. The blood chemistry, determined February 17, showed nonprotein nitrogen, 50 mg, uric acid 7.2 mg, sugar 111 mg, and creatinine, 16 mg. The blood counts are given in table 1.

Study of the cells with Wright, Giemsa and peroxidase stains showed no noteworthy changes in the cells other than those tabulated as monocytes (fig 1). These cells were all about from one and one-half to two times the diameter of neutrophils and only rarely could cells with mature nuclei be found. In the remaining cells the nuclei were obviously immature and showed nuclear patterns varying from a fine spongelike network to the coarser lacing seen in mature monocytes of which very few were seen. The nuclei were oval indented or sometimes bean-shaped. The cytoplasm was dull pale blue and of ground glass appearance and the majority of the cells contained a fine,

typical, lilac, monocytic granulation much finer than leukoblastic or neutrophilic granules. In some of the youngest cells these granules were arranged chiefly about the nuclei, the granules filling the cytoplasm. Only rarely could very young ovoid cells with no granulation be found. In these cells nucleoli were sometimes found. Many of the cells showed marked pseudopod formation or fluting of the edge of the cytoplasm. A few cells showed mitosis. Rare cells indistinguishable from myeloblasts and leukoblasts were found, but it was impossible to trace gradations from these cells to the

Fig. 2 (case 1)—Spleen showing obliteration of architecture by reticular cell overgrowth. High power view.

type cell previously described. In the rare leukoblast the granules were much larger and darker than the granules of the young monocytes. The type cell was peroxidase-negative when stained according to the Goodpasture, Sato and Washburn methods. There was no noteworthy change from day to day in the immaturity of the cells in the various counts tabulated. In fresh moist preparations the cells were actively motile, and in Janus green preparations the dye was found in many small dots throughout the cytoplasm. The red cells showed a slight variation in size and shape and on the average were slightly smaller than normal. A few cells showed polychromatophilia, and an occasional normoblast was found.

On the day after admission, a soft, fleshy node 4 by 4 by 2 cm was removed from the left groin. Sections showed nearly complete obliteration of the normal architecture by a profound overgrowth of reticular cells similar to those in the nodes removed at autopsy, to be described.

Autopsy was done four hours after death.

The anatomic diagnosis was acute leukemic reticulo-endotheliosis with marked enlargement of the spleen and liver, hyperplasia of the bone marrow and diffuse enlargement of the lymph nodes throughout the body, ulcerogangrenous inflammation of the base of the tongue and the throat and gums, reticular cell proliferation in the kidneys, pancreas, serous surfaces, stomach, intestines, liver and all the organs sectioned, hypostatic hyperemia and bronchopneumonia of the lungs, fibrinous pleuritis and peritonitis, moderate icterus, moderate anemia, petechial hemorrhages of the skin and of the pelvis of the kidneys, cloudy swelling of the myocardium with dilatation of the heart.

The necrotic lesion in the base of the tongue extended into both peritonsillar areas and the base of the epiglottis. Marked swelling of the aperture to the larynx and of the false cords, pharynx and palate was also present. The lymph nodes in all groups of the body varied from 1 to 3 cm across and were soft, fleshy and opaque gray-pink on the surfaces made by section. Of particular interest was an organizing fibrinous exudate about the capsule of the spleen, between the liver and diaphragm and on the pleural surfaces. The omentum mesentery and gastrocolic ligament were stiffened by a diffuse soft apparent fibrosis, and the serosa of the posterior abdominal wall was moderately thickened. The liver weighed 2400 Gm

and was light tan-yellow, the markings were just visible. The kidneys were enormous and weighed, together 550 Gm. They were soft and bulged markedly under the capsule when cut, and the surfaces were opaque and gray-yellow. The heart showed nothing abnormal besides dilatation of its chambers. The thymus measured 8 by 5 by 2 cm and resembled the lymph nodes on section. The bone marrow of the femur, ribs, vertebrae and sternum was devoid of fat, gray-pink and fairly firm in consistency and could be removed in a solid chunk from the shaft of the femur.

Histologic sections showed the architecture of the spleen (fig. 2) and the lymph nodes (fig. 2) to be obliterated by a profound growth of reticular cells with oval, indented or bean-shaped vesicular nuclei and a moderate amount of cytoplasm in intimate connection with a fine meshwork of abundant reticulum demonstrated by Foot's silver stain. Mitoses were common. This proliferation distorted the splenic sinuses and the lymph sinuses in the nodes. No evidence of proliferation of endothelium was found. Occasionally a small nest of myeloid cells, apparently myeloblasts, and rarely a clump of nucleated red cells and a rare megakaryocyte were seen in the spleen and the lymph nodes, but these bore no such relation to the reticulum as did the reticular cells. The liver (fig. 4) showed marked proliferation of reticular cells in a large amount of reticulum in the periportal channels. There was no undue proliferation of Kupffer cells. The bone marrow was entirely devoid of fat and the majority of the cells present were similar to those in the spleen, lymph nodes and elsewhere. A moderate number of foci of myelogenous cells and erythropoietic centers and a few megakaryocytes were present. A large amount of fine reticulum was present in between the reticular cells. In all the organs, leukemic cells were found in large numbers in the blood vessels, they were similar to the cells in the reticulum. Sections of the kidney showed marked reticular cell proliferation throughout the organ and profound degenerative changes in the tubules. The thymus (fig. 5) was almost entirely composed of reticular growth. In the intestine the serosa of the entire wall was involved. The pancreas, peribronchial tissues and pleura were likewise the seat of reticular cell and fibrillar overgrowth. In sections of the necrotic area in the throat stained by Warthin's method for spirochetes,

Fig. 3 (case 1)—Lymph node showing overgrowth of reticular cells and marked atrophy of germinal center. Low power view.
